Abstract

We compute the branching ratios for $\mu \rightarrow e\gamma$, $\tau \rightarrow \mu\gamma$ and $\tau \rightarrow e\gamma$ in a supersymmetric model invariant under the flavour symmetry group $A_4 \times Z_3 \times U(1)_{FN}$, in which near tri-bimaximal lepton mixing is naturally predicted. At leading order in the small symmetry breaking parameter u , which is of the same order as the reactor mixing angle θ_{13} , we find that the branching ratios generically scale as u^2 . Applying the current bound on the branching ratio of $\mu \rightarrow e\gamma$ shows that small values of u or $\tan\beta$ are preferred in the model for mass parameters m_{SUSY} and $m_{1/2}$ smaller than 1000 GeV. The bound expected from the on-going MEG experiment will provide a severe constraint on the parameter space of the model either enforcing $u \approx 0.01$ and small $\tan\beta$ or m_{SUSY} and $m_{1/2}$ above 1000 GeV. In the special case of universal soft supersymmetry breaking terms in the flavon sector a cancellation takes place in the amplitudes and the branching ratios scale as u^4 , allowing for smaller slepton masses. The branching ratios for $\tau \rightarrow \mu\gamma$ and $\tau \rightarrow e\gamma$ are predicted to be of the same order as the one for $\mu \rightarrow e\gamma$, which precludes the possibility of observing these τ decays in the near future.

1 Introduction

Flavour violation in the lepton sector (LFV) has been firmly established in neutrino oscillations. A direct evidence of conversion of electron neutrinos into a combination of muon and tau neutrinos is provided by solar neutrino oscillations. In a three neutrino framework atmospheric neutrino data can only be explained by the dominant oscillation of muon neutrinos into tau neutrinos. It is natural to expect that LFV takes place, at least at some level, in other processes such as those involving charged leptons. Flavour violating decays of charged leptons, strictly forbidden in the Standard Model (SM), are indeed allowed as soon as neutrino mass terms are considered. If neutrino masses are the only source of LFV, the effects are too small to be detected, but in most extensions of the SM in which new particles and new interactions with a characteristic scale M are included, the presence of new sources of flavour violation, in particular in the lepton sector, is a generic feature. In a low-energy description, the corresponding effects can be parametrized by higher-dimensional operators describing flavour-violating rare decays of the charged leptons. The dominant terms are represented by dimension six operators, suppressed by two powers of M . The present bounds on the branching ratios [1] of these decays set stringent limits on combinations of the scale M and the coefficients of the involved operators. Typically, for coefficients of order one, the existing bounds require a large scale M , several orders of magnitude larger than the TeV scale. Conversely, to allow for new physics at the TeV scale, coefficients much smaller than one are required, which might suggest the presence of a flavour symmetry.

New physics at the TeV scale supplemented by a flavour symmetry provides an interesting framework. Flavour symmetries have been invoked to describe the observed pattern of lepton masses and mixing angles [2], but quite often this approach is limited to a fit of the existing data, with very few new testable predictions [3]. Specific relations among LFV processes are usually consequences of flavour symmetries and of their pattern of symmetry breaking. This allows to get independent information on the flavour symmetry in the charged lepton sector. Moreover, if M is sufficiently small, new particles might be produced and detected at the LHC, with features that could additionally confirm or reject the assumed symmetry pattern. In [4] we have recently analyzed in an effective Lagrangian approach LFV processes within a class of models possessing a flavour symmetry $G_f = A_4 \times Z_3 \times U(1)_{FN}$. Models of this class [5–8] automatically reproduce nearly tri-bimaximal (TB) lepton mixing at the leading order (LO) via a vacuum alignment mechanism.¹ In this type of models [5–8, 10, 11], corrections to TB mixing are generically proportional to the symmetry breaking parameter u , especially the reactor mixing angle θ_{13} is of the order of u .² The parameter u is expected to vary between a few per mil and a few percent. In particular we have evaluated the normalized branching ratios R_{ij} for the LFV transitions $l_i \rightarrow l_j \gamma$:

$$R_{ij} = \frac{BR(l_i \rightarrow l_j \gamma)}{BR(l_i \rightarrow l_j \nu_i \bar{\nu}_j)} \quad . \quad (1)$$

¹Due to the success of these models in the lepton sector several extensions to the quark sector can be found in the literature [9].

²For alternative scenarios see [12, 13].

In [4] we found that the generic expectation for the ratios R_{ij} is:

$$R_{ij} = \frac{48\pi^3\alpha}{G_F^2 M^4} |w_{ij} u|^2 \quad (2)$$

where α is the fine structure constant, G_F is the Fermi constant and w_{ij} are dimensionless parameters that cannot be predicted within the effective Lagrangian approach, but are expected to be of order one. Given the range of u , it turns out that the present bound on $\mu \rightarrow e\gamma$ requires the scale M to be larger than about 10 TeV. If the underlying fundamental theory is weakly interacting, this translates into a lower bound of about $gM/(4\pi)$ on the typical mass of the new particles. At variance with this generic estimate, it was also observed that, if the flavour symmetry is realized in a supersymmetric (SUSY) model, a cancellation might take place in the amplitudes for LFV transitions. An argument was given suggesting that in this case the ratios R_{ij}^{SUSY} are of the form:

$$R_{ij}^{SUSY} = \frac{48\pi^3\alpha}{G_F^2 M^4} \left[|w_{ij}^{(1)} u|^2 + \frac{m_j^2}{m_i^2} |w_{ij}^{(2)} u|^2 \right] \quad (3)$$

where M now corresponds to the supersymmetry breaking scale, m_i ($i = e, \mu, \tau$) are the charged lepton masses and $w_{ij}^{(1,2)}$ are unknown dimensionless quantities of order one. Therefore in a supersymmetric context the predicted rates are more suppressed, allowing for new physics close to the TeV scale, without conflicting with the present bounds. Since the cancellation expected in the supersymmetric case considerably changes the conclusion that can be derived from the existing bound on $\mu \rightarrow e\gamma$, it is important to perform a direct computation of the branching ratios within an explicit supersymmetric model incorporating the flavour symmetry $A_4 \times Z_3 \times U(1)_{FN}$.

In the present paper we consider the A_4 realization proposed in [4] in which SUSY breaking effects were ignored and we extend it to a more realistic model, by adding a full set of SUSY breaking terms consistent with the flavour symmetry. We assume that the breaking of supersymmetry occurs at a scale higher than or comparable to the flavour scale, simulated in our effective Lagrangian by a cutoff, so that at energies close to the cutoff scale we have non-universal boundary conditions for the soft SUSY breaking terms, dictated by the flavour symmetry. Depending on the assumed mechanism of SUSY breaking we may have boundary conditions different from these, possibly enforced at a smaller energy scale. For this reason, our approach maximizes the possible effects on LFV processes.

Through a detailed calculation of the slepton mass matrices in the physical basis, in which kinetic terms are canonical and leptons are in their mass eigenbasis, and evaluation of R_{ij} in the mass insertion (MI) approximation we find that the behaviour of R_{ij} , expected from the SUSY variant of the effective Lagrangian approach, given in eq. (3) is violated by a single, flavour independent contribution. The correct scaling of R_{ij} is the one of eq. (2), with a universal constant w_{ij} . This implies $R_{\mu e} = R_{\tau\mu} = R_{\tau e}$ at the LO in u . We identify the source of violation of the expected behaviour in a contribution to the right-left (RL) block of the slepton mass matrix, associated to the sector necessary to maintain the correct breaking of the flavour symmetry A_4 . We also enumerate the conditions under which such a contribution is absent and the behavior in eq. (3) is recovered, though we could not find a dynamical explanation to justify the realization of these conditions in our model.

As shown in the MI approximation the coefficient w_{ij} of the leading contribution in eq. (2) is numerically small in a large region of the parameter space, where the sub-leading contributions play an important role. We then provide a numerical study of R_{ij} by using full one-loop expressions and explore the parameter space of the model. Thereby, we assume a supergravity (SUGRA) framework with a common mass scale m_{SUSY} for soft sfermion and Higgs masses and a common mass $m_{1/2}$ for gauginos at high energies. Applying the current MEGA bound on $R_{\mu e}$ we find that small values of u or $\tan\beta$ are favoured for m_{SUSY} and $m_{1/2}$ below 1000 GeV. Employing the foreseen bound coming from the MEG experiment constrains the model severely allowing only for small u and $\tan\beta$ for $m_{SUSY}, m_{1/2} \lesssim 1000$ GeV or requires larger m_{SUSY} and $m_{1/2}$ reducing the prospects for detection of sparticles at LHC. Furthermore, it turns out to be rather unnatural to reconcile the values of superparticle masses necessary to account for the measured deviation δa_μ in a_μ , the muon anomalous magnetic moment, from the SM value with the present bound on $R_{\mu e}$. In our model values of δa_μ smaller than 100×10^{-11} are favoured.

The paper is structured as follows: in section 2 we review the basic features of the SUSY A_4 model and calculate kinetic terms and mass matrices of leptons and sleptons in an expansion in the symmetry breaking parameters. In section 3 we compute the slepton mass matrices in the physical basis. Furthermore, we estimate the possible effects on the slepton masses coming from renormalization group (RG) running. Section 4 is dedicated to the study of the quantities R_{ij} in the MI approximation, while in section 5 we discuss $R_{\mu e}$ in a more quantitative way in the SUGRA context and comment on the size of the measured deviation in the muon anomalous magnetic moment a_μ in our model. Finally, we conclude in section 6. Appendix A contains details about the group theory of A_4 , appendix B details of the calculation of the slepton mass matrices in the physical basis and in appendix C conventions and formulae, used in the numerical study of section 5, are given.

2 A SUSY model with A_4 flavour symmetry

In this section, we first discuss the main features and predictions of the lepton mixing in the class of A_4 realizations to which the present SUSY model belongs. Then we will present the Kähler and the superpotential of our model from which kinetic and mass terms are derived for leptons and sleptons.

2.1 General features

The flavour symmetry A_4 can give rise to TB mixing in the lepton sector, if it is broken in a specific way, as discussed in [5–8, 10]. The group A_4 is the group of even permutations of four objects which is isomorphic to the tetrahedral group. It has 12 elements and four irreducible representations: three inequivalent singlets, denoted by 1, 1' and 1'' and a triplet 3. A_4 is generated by two generators S and T which fulfill the following relations [14]:

$$S^2 = (ST)^3 = T^3 = 1 \quad . \quad (4)$$

A set of generators S and T for all representations as well as Kronecker products and Clebsch Gordan coefficients are given in appendix A. The specific breaking pattern of A_4 which leads to TB mixing for leptons requires that a Z_3 subgroup, called G_T , is preserved in the charged lepton sector, whereas a Z_2 group, G_S , remains unbroken in the neutrino sector. The Z_3 group is generated by the element T and is left intact, if a scalar triplet $\varphi = (\varphi_1, \varphi_2, \varphi_3)$ acquires a vacuum expectation value (VEV) of the form:

$$\langle \varphi \rangle \propto (1, 0, 0) . \quad (5)$$

Breaking A_4 down to G_S is achieved by a triplet which gets a VEV:

$$\langle \varphi \rangle \propto (1, 1, 1) . \quad (6)$$

Apart from A_4 , being responsible for TB mixing, the theory is invariant under additional flavour symmetries so that the full symmetry is:

$$G_f = A_4 \times Z_3 \times U(1)_{FN} \times U(1)_R . \quad (7)$$

The cyclic symmetry Z_3 (not to be confused with the Z_3 subgroup of A_4 preserved at LO in the charged lepton sector) is necessary in order to avoid large mixing effects between the flavons that give masses to the charged leptons and those giving masses to neutrinos. The mass hierarchy among the charged leptons is explained through the $U(1)_{FN}$ factor [15]. The second $U(1)$ factor, $U(1)_R$, is a continuous R -symmetry containing R -parity as a subgroup. The flavour symmetry G_f is broken by the chiral superfields φ_T , φ_S , ξ and θ_{FN} whose transformation properties under G_f are shown in table 1 together with those of the lepton supermultiplets l , e^c , μ^c , τ^c and of the electroweak doublets $H_{u,d}$. Introducing the driving fields φ_0^T , φ_0^S and ξ_0 , see also table 1, we can write down the following superpotential: ³

$$\begin{aligned} w_d = & M_T(\varphi_0^T \varphi_T) + g(\varphi_0^T \varphi_T \varphi_T) \\ & + g_1(\varphi_0^S \varphi_S \varphi_S) + g_2 \tilde{\xi}(\varphi_0^S \varphi_S) + g_3 \xi_0(\varphi_S \varphi_S) + g_4 \xi_0 \xi^2 + g_5 \xi_0 \xi \tilde{\xi} + g_6 \xi_0 \tilde{\xi}^2 + \dots \end{aligned} \quad (8)$$

where dots denote sub-leading non-renormalizable corrections. By $(\dots)$ we denote the contraction to an A_4 invariant. In the limit of unbroken supersymmetry all F terms vanish. From these conditions we can derive the vacuum alignment of the flavons φ_T , φ_S and ξ :

$$\begin{aligned} \frac{\langle \varphi_T \rangle}{\Lambda_f} &= (u, 0, 0) + (c'u^2, cu^2, cu^2) + O(u^3) \\ \frac{\langle \varphi_S \rangle}{\Lambda_f} &= c_b(u, u, u) + O(u^2) \\ \frac{\langle \xi \rangle}{\Lambda_f} &= c_a u + O(u^2) \end{aligned} \quad (9)$$

where $c, c', c_{a,b}$ are complex numbers with absolute value of order one and u is one of the two small symmetry breaking parameters in the theory. The scale Λ_f is the cutoff scale

³The additional flavon field $\tilde{\xi}$ transforms in the same way under the symmetries of the model as the field ξ . However, it does not acquire a VEV at LO and thus is not relevant for our discussion here. For further details see [6].

associated to the flavour symmetry. Its value is expected to be around the scale of grand unification 10^{16} GeV. We display the sub-leading $O(u^2)$ corrections, which arise from non-renormalizable terms in the superpotential w_d and which have been studied in detail in [6], only for the field φ_T , since only these are relevant in the following analysis, whereas those of the fields ξ and φ_S are important in the computation of neutrino masses and lepton mixings. We remark that in the SUSY limit the VEVs of the driving fields φ_0^T , φ_0^S and ξ_0 are zero. This is however in general no longer true, if we include soft SUSY breaking terms into the flavon potential, as we shall see in the next section and as has been discussed in [16].

For the Froggatt-Nielsen (FN) field θ_{FN} to acquire a VEV, we assume that the symmetry $U(1)_{FN}$ is gauged such that θ_{FN} gets its VEV through a D term. The corresponding potential is of the form:

$$V_{D,FN} = \frac{1}{2}(M_{FI}^2 - g_{FN}|\theta_{FN}|^2 + \dots)^2 \quad (10)$$

where g_{FN} is the gauge coupling constant of $U(1)_{FN}$ and M_{FI}^2 denotes the contribution of the Fayet-Iliopoulos (FI) term. Dots in eq.(10) represent e.g. terms involving the right-handed charged leptons e^c and μ^c which are charged under $U(1)_{FN}$. These terms are relevant in the calculation of the different contributions to the soft mass terms of right-right (RR) type, as we shall see below. $V_{D,FN}$ leads in the SUSY limit to:

$$|\langle\theta_{FN}\rangle|^2 = \frac{M_{FI}^2}{g_{FN}} \quad (11)$$

which we parametrize as:

$$\frac{\langle\theta_{FN}\rangle}{\Lambda_f} = t \quad (12)$$

with t being the second small symmetry breaking parameter in our model. Both u and t can also be in general complex, but through field redefinitions of the supermultiplets φ_T and θ_{FN} , they can be made real and positive.

Field	l	e^c	μ^c	τ^c	$H_{u,d}$	φ_T	φ_S	ξ	θ_{FN}	φ_0^T	φ_0^S	ξ_0
A_4	3	1	$1''$	$1'$	1	3	3	1	1	3	3	1
Z_3	ω	ω^2	ω^2	ω^2	1	1	ω	ω	1	1	ω	ω
$U(1)_{FN}$	0	2	1	0	0	0	0	0	-1	0	0	0
$U(1)_R$	1	1	1	1	0	0	0	0	0	2	2	2

Table 1: Transformation properties of the fields under A_4 , Z_3 , $U(1)_{FN}$ and $U(1)_R$.

At the LO, the mass matrices of charged leptons and light neutrinos have the following form:

$$m_l \propto \begin{pmatrix} y_e t^2 & 0 & 0 \\ 0 & y_\mu t & 0 \\ 0 & 0 & y_\tau \end{pmatrix} u \quad , \quad (13)$$

and

$$m_\nu \propto \begin{pmatrix} a + 2b/3 & -b/3 & -b/3 \\ -b/3 & 2b/3 & a - b/3 \\ -b/3 & a - b/3 & 2b/3 \end{pmatrix} u \quad , \quad (14)$$

with y_e, y_μ, y_τ, a and b being complex numbers with absolute values of order one. As one can see the relative hierarchy among the charged lepton masses is given by the parameter t for which we take:

$$t \approx 0.05 \quad . \quad (15)$$

The neutrino mass matrix is diagonalized by:

$$U_{TB}^T m_\nu U_{TB} \propto \text{diag}(a + b, a, -a + b)u \quad , \quad (16)$$

where U_{TB} , up to phases, is the TB mixing matrix [17]:

$$U_{TB} = \begin{pmatrix} \sqrt{2/3} & 1/\sqrt{3} & 0 \\ -1/\sqrt{6} & 1/\sqrt{3} & -1/\sqrt{2} \\ -1/\sqrt{6} & 1/\sqrt{3} & +1/\sqrt{2} \end{pmatrix} \quad . \quad (17)$$

The allowed range of the parameter u is determined by the requirement that sub-leading corrections which perturb the LO result are not too large and by the requirement that the τ Yukawa coupling y_τ does not become too large. The first requirement results in an upper bound on u of about 0.05, which mainly comes from the fact that the solar mixing angle should remain in its 1σ range [2]. The second one gives a lower bound which we estimate as:

$$u = \frac{\tan \beta}{|y_\tau|} \frac{\sqrt{2} m_\tau}{v} \approx 0.01 \frac{\tan \beta}{|y_\tau|} \quad (18)$$

where $v \approx 246$ GeV and $\tan \beta$ is the ratio between the VEVs of the neutral spin zero components of H_u and H_d , the two doublets responsible for electroweak symmetry breaking. For the τ lepton we use its pole mass $m_\tau = (1776.84 \pm 0.17)$ MeV [18]. Requesting $|y_\tau| < 3$ we find a lower limit on u close to the upper bound 0.05 for $\tan \beta = 15$, whereas $\tan \beta = 2$ ⁴ gives as lower limit $u \gtrsim 0.007$. Obviously, these limits depend on the largest allowed value of $|y_\tau|$, as well as on whether we identify m_τ with the pole mass or with the τ mass renormalized at some reference scale, such as the scale of grand unification. We choose as maximal range:

$$0.007 \lesssim u \lesssim 0.05 \quad , \quad (19)$$

which shrinks when $\tan \beta$ is increased from 2 to 15. Concerning the relative size of the two symmetry breaking parameters we note that $u \lesssim t$ holds for all values of u .

⁴It is known that $\tan \beta$ cannot be too small [19]. Here we take $\tan \beta = 2$ as the smallest allowed value.

2.2 The SUSY Lagrangian and the soft SUSY breaking terms

We analyse the Lagrangian of the model:

$$\begin{aligned} \mathcal{L} = & \int d^2\theta d^2\bar{\theta} \mathcal{K}(\bar{z}, e^{2V} z) + \left[\int d^2\theta w(z) + h.c. \right] \\ & + \frac{1}{4} \left[\int d^2\theta f(z) \mathcal{W}\mathcal{W} + h.c. \right] \quad , \end{aligned} \quad (20)$$

where $\mathcal{K}(\bar{z}, z)$ is the Kähler potential, a real gauge-invariant function of the chiral superfields z and their conjugates, of dimensionality (mass)²; $w(z)$ is the superpotential, an analytic gauge-invariant function of the chiral superfields, of dimensionality (mass)³; $f(z)$ is the gauge kinetic function, a dimensionless analytic gauge-invariant function; V is the Lie-algebra valued vector supermultiplet, describing the gauge fields and their superpartners. Finally $\mathcal{W}$ is the chiral superfield describing, together with the function $f(z)$, the kinetic terms of gauge bosons and their superpartners. Each of the terms on the right-hand side can be written in an expansion in powers of the flavon fields. Since we have two independent symmetry breaking parameters, u and t , see eqs. (9) and eq. (12), we consider a double expansion of $\mathcal{L}$ in powers of u and t . In this expansion we keep terms up to the second order in u , i.e. terms quadratic in the fields $\varphi_{S,T}$ and ξ . The expansion in the parameter t , responsible for the breaking of the Froggatt-Nielsen $U(1)_{FN}$ symmetry, is stopped at the first non-trivial order, that is by allowing as many powers of the field θ_{FN} as necessary in order to obtain non-vanishing values for all entries of the matrices describing lepton masses as well as for the entries of the matrices describing kinetic terms and slepton masses.⁵ Finally, second order corrections in u also arise from the sub-leading terms of the VEV $\langle \varphi_T \rangle$, eq. (9), and are included in our estimates.

The soft SUSY breaking terms are generated from the SUSY Lagrangian by promoting all coupling constants, such as Yukawa couplings, couplings in the flavon superpotential and couplings in the Kähler potential, to superfields with constant θ^2 and $\theta^2\bar{\theta}^2$ components [20]. Through this we derive subsequently the soft masses $(m_{(e,\nu)LL}^2)_K$ and $(m_{eRR}^2)_K$ from the Kähler potential. One contribution to m_{eRL}^2 , which we call $(m_{eRL}^2)_1$ in the following, arises from the Yukawa couplings present in the superpotential w .

Important contributions to slepton masses originate from the modification of the VEVs of flavons and driving fields due to SUSY breaking effects. A detailed study of the VEVs of these fields and their dependence on the soft SUSY breaking parameters is presented in [16] and we summarize the main results here. When soft SUSY breaking terms are included into the flavon potential, the VEVs in eq. (9) receive additional contributions of order m_{SUSY} , completely negligible compared to $\Lambda_f u$. At the same time, the driving fields φ_0^T , φ_0^S and ξ_0 develop a VEV of the size of the soft SUSY breaking scale m_{SUSY} . An equivalent statement is that the auxiliary fields of the flavons acquire a VEV at the

⁵Concerning the Kähler potential we observe that we can additionally write down operators involving the total invariant $\bar{\theta}_{FN}\theta_{FN} = |\theta_{FN}|^2$. These contribute to the diagonal elements of the kinetic terms and the slepton masses. In the Kähler potential for the left-handed fields they can be safely neglected, since the LO correction is of $O(u)$. In the right-handed sector, they contribute at the same order as the terms arising through a double flavon insertion.

LO of the size of $m_{SUSY} \times u \Lambda_f$. Especially, for the auxiliary fields contained in the flavon supermultiplet φ_T we have [16]:

$$\frac{1}{\Lambda_f} \left\langle \frac{\partial w}{\partial \varphi_T} \right\rangle = \zeta m_{SUSY} \{ (u, 0, 0) + (c'_F u^2, c_F u^2, c_F u^2) \} \quad (21)$$

where ζ , c'_F and c_F are in general complex numbers with absolute value of order one. The parameter ζ vanishes in the special case of universal soft mass terms in the flavon potential. When different from zero, the VEVs of the auxiliary components of the flavon supermultiplet φ_T generate another contribution to the soft masses of RL-type, which we denote as $(m_{eRL}^2)_2$. This contribution is analogous to the one which has been found before in the supergravity context and which can have a considerable effect on the size of the branching ratio of radiative leptonic decays, as shown in [21, 22]. Indeed, as we shall see below, in the global SUSY model under consideration the leading dependence of the normalized branching ratios R_{ij} on u is dominated by $(m_{eRL}^2)_2$. We remark that the VEVs in eq. (21) and those of the corresponding flavon field φ_T in eq. (9) have a similar structure but they are not proportional, in general. This is due to the different coefficients c , c' and c_F , c'_F , which can be qualitatively understood as follows: the coefficients c , c' mainly depend on a set of parameters that remain in the SUSY limit and receive completely negligible corrections from the SUSY breaking terms. On the contrary $\langle \partial w / \partial \varphi_T \rangle$ vanishes in the SUSY limit, to all orders in u , and c_F , c'_F crucially depend on the set of parameters describing the SUSY breaking. We will see that, if c and c_F accidentally coincide (up to complex conjugation), a cancellation in the leading behaviour of R_{ij} takes place.

Similarly, the VEV of the FN field θ_{FN} becomes shifted, when soft SUSY breaking terms are included into the potential, so that:

$$\frac{M_{FI}^2}{g_{FN}} - |\langle \theta_{FN} \rangle|^2 = c_\theta m_{SUSY}^2, \quad (22)$$

with c_θ being an order one number, holds. This will lead to a contribution $(m_{eRR}^2)_{D,FN}$ to the soft masses of RR-type, since only the right-handed charged leptons e^c and μ^c are charged under $U(1)_{FN}$. Apart from these there are supersymmetric contributions to $m_{(e,\nu)LL}^2$ and m_{eRR}^2 from F and D terms, $(m_{(e,\nu)LL}^2)_{F(D)}$ and $(m_{eRR}^2)_{F(D)}$, as well as a contribution to m_{eRL}^2 coming from the F term of H_d , called $(m_{eRL}^2)_3$ in the following.

In our notation a chiral superfield and its R -parity even component are denoted by the same letter. The R -parity odd component is indicated by a tilde in the following and the conjugate (anti-chiral) superfield is denoted by a bar.

2.2.1 Kähler potential

The expansion of the Kähler potential can be written as:

$$\mathcal{K} = \mathcal{K}^{(0)} + \mathcal{K}^{(1)} + \mathcal{K}^{(2)} + \dots \quad (23)$$

In our model the Kähler potential deviates from the canonical form, $\mathcal{K}(\bar{z}, z) = \bar{z}z$, due to the contributions of non-renormalizable terms, invariant under both the gauge and the flavour symmetries. Such contributions are sub-leading in the (u, t) expansion, but in

principle they are non-negligible, since the redefinitions required to arrive at canonically normalized fields can also affect lepton and slepton mass matrices. The LO term in u is given by:

$$\mathcal{K}^{(0)} = k_0 \sum_{i=1}^3 \bar{l}_i l_i + \sum_{i=1}^3 \left[(k_0^c)_i + (\hat{k}_0^c)_i \frac{|\theta_{FN}|^2}{\Lambda_f^2} \right] \bar{l}_i^c l_i^c + k_u |H_u|^2 + k_d |H_d|^2 + k_{FN} |\theta_{FN}|^2 + \dots \quad (24)$$

where $l^c = (e^c, \mu^c, \tau^c)$ and dots stand for additional contributions related to the flavon sector. The quantities k_0 , $(k_0^c)_i$, $(\hat{k}_0^c)_i$, $k_{u,d}$, k_{FN} and the corresponding ones in the following formulae, are treated as superfields with a constant $\theta^2 \bar{\theta}^2$ component, as is explained above. Concerning the effect of the superfield θ_{FN} on the Kähler potential $\mathcal{K}^{(0)}$ of the supermultiplets l_i and l_i^c note that for our purposes we can neglect such terms, with the exception of the right-handed sector, where terms up to the second order in t have to be taken into account.

At the first order in u we have:

$$\mathcal{K}^{(1)} = \frac{k_S}{\Lambda_f} (\varphi_T(\bar{l}l)_S) + \frac{k_A}{\Lambda_f} (\varphi_T(\bar{l}l)_A) + \frac{k'_S}{\Lambda_f} (\bar{\varphi}_T(\bar{l}l)_S) + \frac{k'_A}{\Lambda_f} (\bar{\varphi}_T(\bar{l}l)_A) + h.c. \quad (25)$$

$(\dots)$ denotes an invariant under A_4 , while $(\dots)'$ and $(\dots)''$ stand for the $1'$ and $1''$ singlets. Finally two A_4 triplets, a and b , can be combined into the symmetric triplet $(ab)_S$ or the anti-symmetric one $(ab)_A$. The $SU(2)$ singlet fields l^c are not affected by the first-order correction $\mathcal{K}^{(1)}$.

At the second order in u we have a richer structure:

$$\mathcal{K}^{(2)} = \mathcal{K}_L^{(2)} + \mathcal{K}_R^{(2)} \quad , \quad (26)$$

with the labels L and R referring to lepton doublets l and singlets l^c , respectively. For lepton doublets we find:

$$\mathcal{K}_L^{(2)} = \sum_{i=1}^7 \frac{k_i}{\Lambda_f^2} (X_i \bar{l}l) \quad (27)$$

where X is the list of Z_3 -invariant operators, bilinear in the flavon superfields $\varphi_{S,T}$ and ξ and their conjugates,

$$X = \{\bar{\xi}\xi, \varphi_T^2, (\bar{\varphi}_T)^2, \bar{\varphi}_T \varphi_T, \bar{\varphi}_S \varphi_S, \bar{\xi} \varphi_S, \bar{\varphi}_S \xi\} \quad , \quad (28)$$

and each quantity k_i represents a list of parameters since there can be different non-equivalent ways of combining X_i with $\bar{l}l$ to form an A_4 -invariant. There are also obvious relations among the coefficients k_i to guarantee that $\mathcal{K}_L^{(2)}$ is real. Note that the sum in eq. (27) runs over all bilinears which can couple to form A_4 -invariants. Whether they lead to a non-trivial contribution to the relevant terms depends on the VEVs of the flavons.

For lepton singlets, we can distinguish a diagonal contribution and a non-diagonal one:

$$\mathcal{K}_R^{(2)} = [\mathcal{K}_R^{(2)}]_d + [\mathcal{K}_R^{(2)}]_{nd} \quad (29)$$

$$[\mathcal{K}_R^{(2)}]_d = \frac{1}{\Lambda_f^2} \sum_{i=1}^5 [(k_e^c)_i (X_i) \bar{e}^c e^c + (k_\mu^c)_i (X_i) \bar{\mu}^c \mu^c + (k_\tau^c)_i (X_i) \bar{\tau}^c \tau^c] \quad (30)$$

$$\begin{aligned}
[\mathcal{K}_R^{(2)}]_{nd} &= \sum_{i=2}^5 \left[\frac{(k_{e\mu}^c)_i}{\Lambda_f^3} (X_i)' \bar{\theta}_{FN} \bar{e}^c \mu^c + h.c. \right] \\
&+ \sum_{i=2}^5 \left[\frac{(k_{e\tau}^c)_i}{\Lambda_f^4} (X_i)'' (\bar{\theta}_{FN})^2 \bar{e}^c \tau^c + h.c. \right] \\
&+ \sum_{i=2}^5 \left[\frac{(k_{\mu\tau}^c)_i}{\Lambda_f^3} (X_i)' \bar{\theta}_{FN} \bar{\mu}^c \tau^c + h.c. \right].
\end{aligned} \tag{31}$$

Due to the structure of the flavon VEVs only the term with $i = 5$ gives a non-vanishing contribution in the sum in eq. (31). In order to generate a set of supersymmetry breaking soft mass terms, the quantities:

$$k_I = \{k_0, (k_0^c)_i, (\hat{k}_0^c)_i, k_{u,d}, k_{FN}, k_S, k_A, k'_S, k'_A, k_j, (k_e^c)_l, (k_\mu^c)_l, (k_\tau^c)_l, (k_{e\mu}^c)_l, (k_{e\tau}^c)_l, (k_{\mu\tau}^c)_l\} \tag{32}$$

are treated as superfields with a constant $\theta^2 \bar{\theta}^2$ component:

$$k_I = p_I + q_I \theta^2 \bar{\theta}^2 m_{SUSY}^2 \tag{33}$$

where p_I and q_I do not depend on the Grassmann variables.⁶ The quantities p_I and q_I are parameters with absolute values of order one. In particular, it is not restrictive to choose (see eq. (24)):

$$k_0 = 1 + q_0 \theta^2 \bar{\theta}^2 m_{SUSY}^2, \quad (k_0^c)_i = 1 + (q_0^c)_i \theta^2 \bar{\theta}^2 m_{SUSY}^2, \tag{34}$$

$$k_{u,d} = 1 + q_{u,d} \theta^2 \bar{\theta}^2 m_{SUSY}^2, \quad k_{FN} = 1 + q_{FN} \theta^2 \bar{\theta}^2 m_{SUSY}^2. \tag{35}$$

When the flavon fields acquire a VEV according to the pattern shown in eqs. (9) and eq. (12), the Kähler potential $\mathcal{K}$ gives rise to non-canonical kinetic terms for lepton and slepton fields of the following form:⁷

$$\begin{aligned}
\mathcal{L}_{kin} &= i K_{ij} \bar{l}_i \bar{\sigma}^\mu D_\mu l_j + i K_{ij}^c \bar{l}_i^c \bar{\sigma}^\mu D_\mu l_j^c \\
&+ K_{ij} \overline{D^\mu \tilde{l}_i} D_\mu \tilde{l}_j + K_{ij}^c \overline{D^\mu \tilde{l}_i^c} D_\mu \tilde{l}_j^c
\end{aligned} \tag{36}$$

The matrices K and K^c are given by:

$$K = \begin{pmatrix} 1 + 2t_1 u & t_4 u^2 & t_5 u^2 \\ \bar{t}_4 u^2 & 1 - (t_1 + t_2) u & t_6 u^2 \\ \bar{t}_5 u^2 & \bar{t}_6 u^2 & 1 - (t_1 - t_2) u \end{pmatrix}, \tag{37}$$

⁶In principle we could allow for a more general expansion in the Grassmann variables θ and/or $\bar{\theta}$, including also terms proportional to θ^2 and to $\bar{\theta}^2$. These terms can be absorbed in our parametrization after a suitable redefinition of the parameters.

⁷We adopt two-component spinor notation, so for example e ($\bar{e}^c$) denotes the left-handed (right-handed) component of the electron field. For instance, in terms of the four-component spinor $\psi_e^T = (e \ \bar{e}^c)$, the bilinears $\bar{e} \bar{\sigma}^\nu e$ and $e^c \sigma^\nu \bar{e}^c$ correspond to $\bar{\psi}_e \gamma^\nu P_L \psi_e$ and $\bar{\psi}_e \gamma^\nu P_R \psi_e$ [$P_{L,R} = \frac{1}{2}(1 \mp \gamma^5)$] respectively. We take $\sigma^\mu \equiv (1, \vec{\sigma})$, $\bar{\sigma}^\mu \equiv (1, -\vec{\sigma})$, $\sigma^{\mu\nu} \equiv \frac{1}{4}(\sigma^\mu \bar{\sigma}^\nu - \sigma^\nu \bar{\sigma}^\mu)$, $\bar{\sigma}^{\mu\nu} \equiv \frac{1}{4}(\bar{\sigma}^\mu \sigma^\nu - \bar{\sigma}^\nu \sigma^\mu)$ and $g_{\mu\nu} = \text{diag}(+1, -1, -1, -1)$, where $\vec{\sigma} = (\sigma^1, \sigma^2, \sigma^3)$ are the 2×2 Pauli matrices. Here the four-component matrix γ^μ is in the chiral basis, where the 2×2 blocks along the diagonal vanish, the upper-right block is given by σ^μ and the lower-left block is equal to $\bar{\sigma}^\mu$.

$$K^c = \begin{pmatrix} 1 + t_1^c u^2 + t_1'^c t^2 & t_4^c u^2 t & t_5^c u^2 t^2 \\ \bar{t}_4^c u^2 t & 1 + t_2^c u^2 + t_2'^c t^2 & t_6^c u^2 t \\ \bar{t}_5^c u^2 t^2 & \bar{t}_6^c u^2 t & 1 + t_3^c u^2 + t_3'^c t^2 \end{pmatrix} . \quad (38)$$

The coefficients $t_{1,2}$, $t_{1,2,3}^c$ and $t_{1,2,3}'^c$ are real, while the remaining coefficients are complex. As one can see, the corrections to the kinetic terms which render these non-canonical are small, at most at order $O(u)$ and $O(t^2)$. They have to be taken into account when calculating lepton and slepton masses. The coefficients t_i and t_i^c are linearly related to the parameters p_I introduced before, see eq. (33). Such a relation is not particularly significant and in the rest of this paper we will treat t_i and t_i^c as input parameters, with absolute values of order one.

Notice that we have neglected possible sub-leading contributions to the kinetic terms of $H_{u,d}$, and to the flavons themselves and θ_{FN} , which have no impact on the present analysis. Note further that through the expansion of $k_{u,d}$ as given in eq. (35) also the soft masses $m_{H_{u,d}}^2$ for the Higgs doublets H_u and H_d are generated of size $q_{u,d} m_{SUSY}^2$. Similarly, the expansion of k_{FN} gives rise to a soft mass term for θ_{FN} of size $q_{FN} m_{SUSY}^2$.

2.2.2 Superpotential

We continue with the discussion of the superpotential:

$$w = w_l + w_\nu + w_d + w_h + \dots \quad (39)$$

There is a part responsible for the charged lepton masses:

$$w_l = w_l^{(1)} + w_l^{(2)} + \dots \quad (40)$$

The leading term in the u expansion is:

$$w_l^{(1)} = \frac{x_e}{\Lambda_f^3} \theta_{FN}^2 e^c H_d (\varphi_T l) + \frac{x_\mu}{\Lambda_f^2} \theta_{FN} \mu^c H_d (\varphi_T l)' + \frac{x_\tau}{\Lambda_f} \tau^c H_d (\varphi_T l)'' \quad . \quad (41)$$

At the next order in u we find:

$$w_l^{(2)} = \frac{x_e'}{\Lambda_f^4} \theta_{FN}^2 e^c H_d (\varphi_T^2 l) + \frac{x_\mu'}{\Lambda_f^3} \theta_{FN} \mu^c H_d (\varphi_T^2 l)' + \frac{x_\tau'}{\Lambda_f^2} \tau^c H_d (\varphi_T^2 l)'' \quad . \quad (42)$$

To generate both the Yukawa interactions and the soft mass contribution $(m_{eRL}^2)_1$, we regard the quantities x_f and x_f' as constant superfields, of the type:

$$x_f = y_f - z_f \theta^2 m_{SUSY} \quad , \quad x_f' = y_f' - z_f' \theta^2 m_{SUSY} \quad (f = e, \mu, \tau) \quad , \quad (43)$$

where the coefficients y_f , z_f , y_f' and z_f' have absolute values of order one. From eqs. (41) and (42), after the breaking of the flavour and the electroweak symmetries, we find the following mass matrix for the charged leptons:

$$m_l = \begin{pmatrix} y_e t^2 u + (y_e' + c' y_e) t^2 u^2 & c y_e t^2 u^2 & c y_e t^2 u^2 \\ c y_\mu t u^2 & y_\mu t u + (y_\mu' + c' y_\mu) t u^2 & c y_\mu t u^2 \\ c y_\tau u^2 & c y_\tau u^2 & y_\tau u + (y_\tau' + c' y_\tau) u^2 \end{pmatrix} \frac{v \cos \beta}{\sqrt{2}} \quad (44)$$

Note that the matrix m_l is shown in the basis in which the kinetic terms for the lepton fields are given by eqs. (36,37,38). At the LO in the u expansion, m_l matches the matrix shown in eq. (13). The off-diagonal elements of m_l , all proportional to c , originate from the sub-leading contributions to the VEV of the φ_T multiplet. Similarly, the superpotential giving rise to neutrino masses can be expanded as:

$$w_\nu = w_\nu^{(1)} + w_\nu^{(2)} + \dots \quad (45)$$

with the LO terms:

$$w_\nu^{(1)} = \frac{x_a}{\Lambda_f \Lambda_L} \xi(H_u l H_u l) + \frac{x_b}{\Lambda_f \Lambda_L} (\varphi_S H_u l H_u l) \quad , \quad (46)$$

where Λ_L is the scale at which lepton number is violated. Also in this case $x_{a,b}$ are constant superfields:

$$x_{a,b} = y_{a,b} + z_{a,b} \theta^2 m_{SUSY} \quad . \quad (47)$$

The terms in $w_\nu^{(1)}$ lead to the form of m_ν as in eq. (14) with $a = y_a c_a$ and $b = y_b c_b$. The next term in the expansion $w_\nu^{(2)}$ is not relevant for our discussion here, however gives rise to deviations of relative order u from TB mixing. The form of w_d , responsible for the vacuum alignment of the flavon fields, has already been displayed above in eq. (8). Finally, the term w_h is associated with the μ parameter:

$$w_h = \mu H_u H_d \quad . \quad (48)$$

This term explicitly breaks the (continuous) $U(1)_R$ symmetry of the model, while preserving R -parity. The μ term might originate from the Kähler potential of the theory [23], after SUSY breaking:

$$\frac{1}{\Lambda} \int d^2\theta d^2\bar{\theta} (\bar{X} H_u H_d + h.c.) \quad (49)$$

where Λ is some large scale as, for instance, the Planck scale and X is a chiral superfield, whose F component F_X develops a VEV. This gives rise to $\mu = \langle F_X \rangle / \Lambda$. In our model we simply assume the existence of the term in eq. (48) in the superpotential and allow for an explicit breaking of the $U(1)_R$ symmetry controlled by the parameter μ . The soft SUSY breaking term $B\mu$ can then arise from the μ term by considering μ as superfield $\mu + \theta^2 B\mu$. A source of the μ term within our model are terms which involve one driving field, a certain number of flavons and the two Higgs doublets H_u and H_d . The lowest order term in the superpotential w , allowed by all symmetries of the model, is:

$$(\varphi_0^T \varphi_T) H_u H_d / \Lambda_f \quad . \quad (50)$$

This term generates a contribution to the μ term of the order of $m_{SUSY} \times u$, when the driving fields acquire VEVs through the inclusion of soft SUSY breaking terms into the flavon potential [16]. The size of such a term is expected to be $\lesssim 50$ GeV for $m_{SUSY} \sim O(1\text{TeV})$.

2.2.3 Slepton masses

From the Kähler potential and the superpotential we can read off the slepton masses; they can be parametrized as follows:

$$-\mathcal{L}_m \supset \sum_{i,j=1}^3 \left[\tilde{e}_i (m_{eLL}^2)_{ij} \tilde{e}_j + \tilde{e}_i (m_{eLR}^2)_{ij} \tilde{e}_j^c + \tilde{e}_i^c (m_{eRL}^2)_{ij} \tilde{e}_j + \tilde{e}_i^c (m_{eRR}^2)_{ij} \tilde{e}_j^c \right] + \sum_{i,j=1}^3 \tilde{\nu}_i (m_{\nu LL}^2)_{ij} \tilde{\nu}_j \quad (51)$$

where $m_{(e,\nu)LL}^2$ and m_{eRR}^2 are hermitian matrices and $m_{eLR}^2 = (m_{eRL}^2)^\dagger$. In the sneutrino sector only the block $m_{\nu LL}^2$ is present. We neglect contributions to the sneutrino masses associated to w_ν . Each of these blocks receives several contributions:

$$\begin{aligned} m_{(e,\nu)LL}^2 &= (m_{(e,\nu)LL}^2)_K + (m_{(e,\nu)LL}^2)_F + (m_{(e,\nu)LL}^2)_D \quad , \\ m_{eRR}^2 &= (m_{eRR}^2)_K + (m_{eRR}^2)_F + (m_{eRR}^2)_D + (m_{eRR}^2)_{D,FN} \quad . \end{aligned} \quad (52)$$

The contribution to the slepton masses from the SUSY breaking terms in the Kähler potential is given by:

$$(m_{eLL}^2)_K = (m_{\nu LL}^2)_K = \begin{pmatrix} n_0 + 2n_1 u & n_4 u^2 & n_5 u^2 \\ \bar{n}_4 u^2 & n_0 - (n_1 + n_2) u & n_6 u^2 \\ \bar{n}_5 u^2 & \bar{n}_6 u^2 & n_0 - (n_1 - n_2) u \end{pmatrix} m_{SUSY}^2 \quad , \quad (53)$$

$$(m_{eRR}^2)_K = \begin{pmatrix} n_1^c & n_4^c u^2 t & n_5^c u^2 t^2 \\ \bar{n}_4^c u^2 t & n_2^c & n_6^c u^2 t \\ \bar{n}_5^c u^2 t^2 & \bar{n}_6^c u^2 t & n_3^c \end{pmatrix} m_{SUSY}^2 \quad , \quad (54)$$

where the coefficients are complex, except for $n_{0,1,2}$ and $n_{1,2,3}^c$.⁸ The coefficients n_i and n_i^c are linearly related to the parameters q_I introduced in eq. (33). Again, such a relation is not particularly significant and in the rest of this paper we will treat n_i and n_i^c as input parameters, with absolute values of order one.

The SUSY contribution from the F terms is completely negligible for sneutrinos, i.e. $(m_{\nu LL}^2)_F = 0$. For charged sleptons $(m_{eLL}^2)_F$ and $(m_{eRR}^2)_F$ read:

$$(m_{eLL}^2)_F = m_l^\dagger (K^c)^{-1} m_l \quad , \quad (m_{eRR}^2)_F = m_l (K^{-1})^T m_l^\dagger \quad , \quad (55)$$

where m_l is the charged lepton mass matrix and K , K^c are the matrices specifying the kinetic terms, eqs. (37) and (38).

The SUSY D term contribution is:

$$\begin{aligned} (m_{eLL}^2)_D &= \left(-\frac{1}{2} + \sin^2 \theta_W \right) \cos 2\beta \, m_Z^2 K \quad , \\ (m_{\nu LL}^2)_D &= \left(+\frac{1}{2} \right) \cos 2\beta \, m_Z^2 K \quad , \\ (m_{eRR}^2)_D &= (-1) \sin^2 \theta_W \cos 2\beta \, m_Z^2 (K^c)^T \quad , \end{aligned} \quad (56)$$

⁸Additionally, we assume that n_0 and $n_{1,2,3}^c$ are positive in order to have positive definite square-masses, to avoid electric-charge breaking minima and further sources of electroweak symmetry breaking.

where m_Z is the Z mass and θ_W is the Weinberg angle. Notice again the presence of the matrices K and K^c .

For the right-handed charged leptons we find an additional D term contribution stemming from the fact that θ_{FN} , e^c and μ^c are charged under the Froggatt-Nielsen symmetry $U(1)_{FN}$, which we assume to be gauged. The relevant contribution of the $U(1)_{FN}$ group to the scalar potential (through a D term) is:

$$\begin{aligned} V_{D,FN} &= \frac{1}{2} \left(M_{FI}^2 + g_{FN} Q_{FN}^i \frac{\partial \mathcal{K}}{\partial z_i} z_i \right)^2 + q_{FN} m_{SUSY}^2 |\theta_{FN}|^2 \\ &= g_{FN}^2 c_\theta m_{SUSY}^2 \left(2|\tilde{e}^c|^2 + |\tilde{\mu}^c|^2 + t_4^c u^2 t \tilde{e}^c \tilde{\mu}^c + \bar{t}_4^c u^2 t \tilde{\mu}^c \tilde{e}^c \right) + \dots \end{aligned} \quad (57)$$

where Q_{FN}^i stands for the FN charge of the scalar field z_i , and in the second line we have displayed only the leading contribution to the terms quadratic in the matter fields. One can check that this contribution is of a similar form and size as the one originating from the Kähler potential, $(m_{eRR}^2)_K$. Thus, we can simply absorb it by redefining the -anyway-unknown coefficients n_i^c , $i = 1, \dots, 6$ parametrizing $(m_{eRR}^2)_K$ in eq. (54).

Concerning the block m_{eRL}^2 , this receives three contributions:

$$m_{eRL}^2 = (m_{eRL}^2)_1 + (m_{eRL}^2)_2 + (m_{eRL}^2)_3. \quad (58)$$

The first one originates from the superpotential, eqs. (41) and (42), and is proportional to the parameters z_f and z'_f of the decomposition in eq. (43):

$$(m_{eRL}^2)_1 = A_1 \frac{v \cos \beta}{\sqrt{2}} m_{SUSY} \quad (59)$$

with

$$A_1 = \begin{pmatrix} z_e t^2 u + (z'_e + c' z_e) t^2 u^2 & c z_e t^2 u^2 & c z_e t^2 u^2 \\ c z_\mu t u^2 & z_\mu t u + (z'_\mu + c' z_\mu) t u^2 & c z_\mu t u^2 \\ c z_\tau u^2 & c z_\tau u^2 & z_\tau u + (z'_\tau + c' z_\tau) u^2 \end{pmatrix}. \quad (60)$$

The second one is related to the fact that the auxiliary fields of the flavon supermultiplet φ_T acquire non-vanishing VEVs of the form as shown in eq. (21), when soft SUSY breaking terms are included into the flavon potential. Formally the contribution can be written as:

$$\overline{\left\langle \frac{\partial w}{\partial \varphi_T} \right\rangle} \left\langle \frac{\partial^3 w}{\partial \varphi_T \partial e_i^c \partial l_j} \right\rangle \tilde{e}_i^c \tilde{e}_j + h.c. \quad (61)$$

so that the soft mass matrix $(m_{eRL}^2)_2$ reads:

$$(m_{eRL}^2)_2 = A_2 \frac{v \cos \beta}{\sqrt{2}} m_{SUSY} \quad (62)$$

with

$$A_2 = \bar{\zeta} \begin{pmatrix} y_e t^2 u + (2y'_e + \bar{c}'_F y_e) t^2 u^2 & \bar{c}'_F y_e t^2 u^2 & \bar{c}'_F y_e t^2 u^2 \\ \bar{c}'_F y_\mu t u^2 & y_\mu t u + (2y'_\mu + \bar{c}'_F y_\mu) t u^2 & \bar{c}'_F y_\mu t u^2 \\ \bar{c}'_F y_\tau u^2 & \bar{c}'_F y_\tau u^2 & y_\tau u + (2y'_\tau + \bar{c}'_F y_\tau) u^2 \end{pmatrix}. \quad (63)$$

The third contribution is proportional to the charged lepton mass matrix and is enhanced in the large $\tan \beta$ regime:

$$(m_{eRL}^2)_3 = -\bar{\mu} \tan \beta m_l \quad . \quad (64)$$

We remark that the origins of the second and the third contribution are quite similar, since both arise from the auxiliary component of a superfield: the second one is attributed to the auxiliary component of the flavon superfield φ_T , while the third one originates from the auxiliary component associated to the Higgs doublet H_d .

3 The physical basis and its stability under renormalization group running

In this section we first discuss the results for the slepton masses in the physical basis and comment on results found in the literature. In the second part, we give an estimate of the renormalization group effects on the slepton masses and show in the leading logarithmic approximation that these effects can be neglected or absorbed into the parametrization of the soft mass terms.

3.1 Slepton masses in the physical basis

All matrices above are given in the basis in which the kinetic terms of the slepton and lepton fields are non-canonical. To derive the physical masses and the unitary transformations that enter our computation, we have to go into a basis in which kinetic terms are canonical, for both, slepton and lepton, fields. Subsequently, we diagonalize the mass matrix of the charged leptons via a biunitary transformation. To avoid flavour-violating gaugino-lepton-slepton vertices in this intermediate step, we perform the same transformation on both fermion and scalar components of the involved chiral superfields. This procedure, described in detail in appendix B, gives us the physical slepton mass matrices $\hat{m}_{(e,\nu)LL}^2$, $\hat{m}_{eRR}^2$ and $\hat{m}_{eRL}^2$. The results shown here are obtained under the assumption that all parameters of the model are real. The analytical expressions for the slepton mass matrices in the physical basis contain the first non-vanishing order in each of the matrix elements. We start with the left-left (LL) block. The contribution from the soft breaking terms is common to charged sleptons and sneutrinos and reads:

$$\begin{aligned} (\hat{m}_{eLL}^2)_K &= (\hat{m}_{\nu LL}^2)_K \\ &= \begin{pmatrix} n_0 + 2 \hat{n}_1 u & (\hat{n}_4 + (3 \hat{n}_1 + \hat{n}_2) c) u^2 & (\hat{n}_5 + (3 \hat{n}_1 - \hat{n}_2) c) u^2 \\ (\hat{n}_4 + (3 \hat{n}_1 + \hat{n}_2) c) u^2 & n_0 - (\hat{n}_1 + \hat{n}_2) u & (\hat{n}_6 - 2 \hat{n}_2 c) u^2 \\ (\hat{n}_5 + (3 \hat{n}_1 - \hat{n}_2) c) u^2 & (\hat{n}_6 - 2 \hat{n}_2 c) u^2 & n_0 - (\hat{n}_1 - \hat{n}_2) u \end{pmatrix} m_{SUSY}^2 \\ \hat{n}_i &= n_i - t_i n_0 \quad \text{for } i = 1, 2, 4, 5, 6 \end{aligned} \quad (65)$$

The supersymmetric F and D term contributions are given by:

$$(\hat{m}_{eLL}^2)_F = \hat{m}_l^T \hat{m}_l \quad , \quad (\hat{m}_{\nu LL}^2)_F = 0 \quad (66)$$

and

$$(\hat{m}_{eLL}^2)_D = \left(-\frac{1}{2} + \sin^2 \theta_W\right) \cos 2\beta m_Z^2 \times \mathbb{1} \quad , \quad (\hat{m}_{\nu LL}^2)_D = \left(+\frac{1}{2}\right) \cos 2\beta m_Z^2 \times \mathbb{1} \quad , \quad (67)$$

with $\hat{m}_l$ being the mass matrix for the charged leptons in the same basis, i.e. diagonal and with canonically normalized kinetic terms. The supersymmetric D term contributions are proportional to the unit matrix. Notice that in the physical basis all SUSY contributions are diagonal in flavour space. Both, the F and the D term, contributions are small compared to that coming from the Kähler potential. The relative suppression is of order $\hat{m}_l^T \hat{m}_l / m_{SUSY}^2$ and m_Z^2 / m_{SUSY}^2 , respectively, which do not exceed the per cent level for typical values of m_{SUSY} around 1 TeV. Note also that the SUSY part is the only one that distinguishes between charged sleptons and sneutrinos. The dominant mass matrix, $(\hat{m}_{eLL}^2)_K = (\hat{m}_{\nu LL}^2)_K$, has a structure which is very similar to that of the corresponding matrix in the original basis, i.e. all matrix elements in the two bases are of the same order in the (u, t) expansion. They only differ for coefficients of order one.

For $\hat{m}_{eRR}^2$ we find that $(\hat{m}_{eRR}^2)_K$ is given by:

$$(\hat{m}_{eRR}^2)_K = \begin{pmatrix} n_1^c & 2c(n_1^c - n_2^c) \frac{m_e}{m_\mu} u & 2c(n_1^c - n_3^c) \frac{m_e}{m_\tau} u \\ 2c(n_1^c - n_2^c) \frac{m_e}{m_\mu} u & n_2^c & 2c(n_2^c - n_3^c) \frac{m_\mu}{m_\tau} u \\ 2c(n_1^c - n_3^c) \frac{m_e}{m_\tau} u & 2c(n_2^c - n_3^c) \frac{m_\mu}{m_\tau} u & n_3^c \end{pmatrix} m_{SUSY}^2 \quad . \quad (68)$$

The supersymmetric terms are:

$$(\hat{m}_{eRR}^2)_F = \hat{m}_l \hat{m}_l^T \quad \text{and} \quad (\hat{m}_{eRR}^2)_D = -\sin^2 \theta_W \cos 2\beta m_Z^2 \times \mathbb{1} \quad . \quad (69)$$

Also in this case the SUSY contributions are diagonal and numerically negligible in most of our parameter space. The dominant contribution is thus $(\hat{m}_{eRR}^2)_K$. We note that $(\hat{m}_{eRR}^2)_K$ at variance with $(\hat{m}_{(e,\nu)LL}^2)_K$ does not depend on the parameters describing the non-canonical kinetic terms. Comparing the size of the entries of $(\hat{m}_{eRR}^2)_K$ with those of $(m_{eRR}^2)_K$ we see that the diagonal elements are still of the same order in t and u , whereas all off-diagonal elements are enhanced by a factor $1/u$. This can be understood in terms of the rotation done on the right-handed leptons to diagonalize the charged lepton mass matrix. Such a rotation is characterized by small angles proportional to $c y_e / y_\mu t u$, $c y_e / y_\tau t^2 u$ and $c y_\mu / y_\tau t u$ in the sectors 12, 13 and 23, respectively. By making the same rotation on the corresponding right-handed sleptons, we obtain the off-diagonal terms of $\hat{m}_{eRR}^2$.

Finally, coming to the RL block of the mass matrix for charged sleptons, we find:

$$(\hat{m}_{eRL}^2)_1 = \begin{pmatrix} \frac{z_e}{y_e} m_e & 2c \frac{(z_e y_\mu - z_\mu y_e)}{y_e y_\mu} m_e u & 2c \frac{(z_e y_\tau - z_\tau y_e)}{y_e y_\tau} m_e u \\ c \frac{(z_\mu y'_\mu - z'_\mu y_\mu)}{y_\mu^2} m_\mu u^2 & \frac{z_\mu}{y_\mu} m_\mu & 2c \frac{(z_\mu y_\tau - z_\tau y_\mu)}{y_\mu y_\tau} m_\mu u \\ c \frac{(z_\tau y'_\tau - z'_\tau y_\tau)}{y_\tau^2} m_\tau u^2 & c \frac{(z_\tau y'_\tau - z'_\tau y_\tau)}{y_\tau^2} m_\tau u^2 & \frac{z_\tau}{y_\tau} m_\tau \end{pmatrix} m_{SUSY} \quad , \quad (70)$$

$$(\hat{m}_{eRL}^2)_2 = \zeta \begin{pmatrix} m_e & (c_F - c) m_e u & (c_F - c) m_e u \\ (c_F - c) m_\mu u & m_\mu & (c_F - c) m_\mu u \\ (c_F - c) m_\tau u & (c_F - c) m_\tau u & m_\tau \end{pmatrix} m_{SUSY} , \quad (71)$$

and

$$(\hat{m}_{eRL}^2)_3 = -\mu \tan \beta \hat{m}_l . \quad (72)$$

The matrix $\hat{m}_{eRL}^2$, which is the sum of these three contributions, does not depend on the parameters describing the non-canonical kinetic terms through K and K^c . An important feature of $(\hat{m}_{eRL}^2)_1$ is that the elements below the diagonal are suppressed by a factor u compared to the corresponding elements of $(m_{eRL}^2)_1$, i.e. before the transformations for canonical normalization of the kinetic terms and diagonalization of the charged lepton mass matrix are applied. However, this does not happen for the second contribution associated to the non-vanishing VEVs of the auxiliary components of the supermultiplet φ_T so that the elements of $(\hat{m}_{eRL}^2)_2$ are still of the same order in the expansion parameters t and u as those of the matrix $(m_{eRL}^2)_2$. Nevertheless there are cases in which this contribution can be suppressed. In the first case the VEVs of the auxiliary fields contained in the supermultiplet φ_T vanish, i.e. the parameter ζ is zero, due to the fact that the soft SUSY breaking terms in the flavon potential are (assumed to be) universal, that is equal to the terms of the superpotential w_d up to an overall proportionality constant [16]. The second possibility arises, if the VEVs of the auxiliary fields can be completely aligned with those of the flavon φ_T at LO as well as NLO, such that c_F becomes equal to c . In both cases the off-diagonal elements of $(\hat{m}_{eRL}^2)_2$ are further suppressed than shown in eq. (71). We emphasize this fact here, since it turns out that the suppression of the off-diagonal elements below the diagonal as it occurs in the case of $(\hat{m}_{eRL}^2)_1$ is relevant for the actual size of the leading behaviour of the normalized branching ratios R_{ij} with respect to the expansion in u . As we shall see in section 4, in a general case $R_{ij} \propto u^2$ holds, whereas, if the contribution in eq. (71) vanishes or is also suppressed, R_{ij} is proportional to u^4 . The contribution $(\hat{m}_{eRL}^2)_3$ is diagonal in flavour space. Concerning the possible size of this contribution, note that $|\mu| \tan \beta / m_{SUSY}$ is the relative magnitude of the non-vanishing elements of $(\hat{m}_{eRL}^2)_3$ with respect to the corresponding ones in $(\hat{m}_{eRL}^2)_{1,2}$. Notice finally that the (31) and (32) element of $\hat{m}_{eRL}^2$ coincide.

We can compare our results with those found in [24], where the slepton mass matrices for a model possessing the same flavour symmetry were also estimated in a similar framework. The main difference between the two setups is that in our model SUSY is a softly broken global symmetry, whereas in [24] the model has been embedded into SUGRA. We agree on the structure of the matrix $(\hat{m}_{eLL}^2)_K$ ($\tilde{m}_L^2$ in the notation of [24]). Concerning the matrix $(\hat{m}_{eRR}^2)_K$ ($\tilde{m}_R^2$ in [24]), we see that the off-diagonal matrix elements of $\tilde{m}_R^2$ are all of order u^2 , whereas we find that those of $(\hat{m}_{eRR}^2)_K$ are of order u . Such a discrepancy has a minor impact on the estimate of the rates for the radiative transitions, since, as we shall see in the next section, the RR block gives a subdominant contribution. It is interesting to note that also in the SUGRA context analyzed in [24] the VEVs of the auxiliary components of the flavon supermultiplets give rise to $(\tilde{m}_{LR}^2)_{21} \approx m_\mu m_{SUSY} u$, which corresponds to our $(\hat{m}_{eRL}^2)_{2,21} \approx m_\mu m_{SUSY} u$, with similar implication on the rate of $\mu \rightarrow e\gamma$.

3.2 Estimate of renormalization group effects

Here we briefly comment on possible effects of the running from the scale $\Lambda_f \approx \Lambda_L$ at which the sfermion masses originate in our effective theory, down to the low energy scale, at which the amplitudes of LFV transitions are evaluated. The renormalization group equations for the soft mass terms $(\hat{m}_{(e,\nu)LL}^2)_K$, $(\hat{m}_{eRR}^2)_K$ and $\hat{A}_e \equiv \sqrt{2}[(\hat{m}_{eRL}^2)_1 + (\hat{m}_{eRL}^2)_2]/(v \cos \beta)$, denoting $t' \equiv \log(\Lambda_L/m_{SUSY})$, are [25]:

$$\begin{aligned}
16\pi^2 \frac{d}{dt'} (\hat{m}_{eLL}^2)_{Kij} &= - \left(\frac{6}{5} g_1^2 |M_1|^2 + 6g_2^2 |M_2|^2 \right) \delta_{ij} - \frac{3}{5} g_1^2 S \delta_{ij} \\
&+ \left((\hat{m}_{eLL}^2)_K \hat{Y}_e^\dagger \hat{Y}_e + \hat{Y}_e^\dagger \hat{Y}_e (\hat{m}_{eLL}^2)_K \right)_{ij} \\
&+ 2 \left(\hat{Y}_e^\dagger (\hat{m}_{eRR}^2)_K \hat{Y}_e + m_{H_d}^2 \hat{Y}_e^\dagger \hat{Y}_e + \hat{A}_e^\dagger \hat{A}_e \right)_{ij}, \\
16\pi^2 \frac{d}{dt'} (\hat{m}_{eRR}^2)_{Kij} &= - \frac{24}{5} g_1^2 |M_1|^2 \delta_{ij} + \frac{6}{5} g_1^2 S \delta_{ij} \\
&+ 2 \left((\hat{m}_{eRR}^2)_K \hat{Y}_e \hat{Y}_e^\dagger + \hat{Y}_e \hat{Y}_e^\dagger (\hat{m}_{eRR}^2)_K \right)_{ij} \\
&+ 4 \left(\hat{Y}_e (\hat{m}_{eLL}^2)_K \hat{Y}_e^\dagger + m_{H_d}^2 \hat{Y}_e \hat{Y}_e^\dagger + \hat{A}_e \hat{A}_e^\dagger \right)_{ij}, \\
16\pi^2 \frac{d}{dt'} (\hat{A}_e)_{ij} &= \left(-\frac{9}{5} g_1^2 - 3g_2^2 + 3\text{Tr}(\hat{Y}_d^\dagger \hat{Y}_d) + \text{Tr}(\hat{Y}_e^\dagger \hat{Y}_e) \right) (\hat{A}_e)_{ij} \\
&+ 2 \left(\frac{9}{5} g_1^2 M_1 + 3g_2^2 M_2 + 3\text{Tr}(\hat{Y}_d^\dagger \hat{A}_d) + \text{Tr}(\hat{Y}_e^\dagger \hat{A}_e) \right) \hat{Y}_{eij} \\
&+ 4 \left(\hat{Y}_e \hat{Y}_e^\dagger \hat{A}_e \right)_{ij} + 5 \left(\hat{A}_e \hat{Y}_e^\dagger \hat{Y}_e \right)_{ij}, \\
16\pi^2 \frac{d}{dt'} \hat{Y}_{eij} &= \left(-\frac{9}{5} g_1^2 - 3g_2^2 + 3\text{Tr}(\hat{Y}_d \hat{Y}_d^\dagger) + \text{Tr}(\hat{Y}_e \hat{Y}_e^\dagger) \right) \hat{Y}_{eij} \\
&+ 3 \left(\hat{Y}_e \hat{Y}_e^\dagger \hat{Y}_e \right)_{ij},
\end{aligned} \tag{73}$$

where $g_{1,2}$ are the gauge couplings⁹ of $SU(2)_L \times U(1)_Y$, $M_{1,2}$ the corresponding gaugino mass terms, $\hat{Y}_{e,d} \equiv \sqrt{2}\hat{m}_{l,d}/(v \cos \beta)$ are the Yukawa matrices for charged leptons and down quarks, $\hat{A}_d = \sqrt{2}[(\hat{m}_{dRL}^2)_1 + (\hat{m}_{dRL}^2)_2]/(v \cos \beta)$ and:

$$S = \text{Tr}(\hat{m}_{qLL}^2 + \hat{m}_{dRR}^2 - 2\hat{m}_{uRR}^2 - (\hat{m}_{eLL}^2)_K + (\hat{m}_{eRR}^2)_K) - m_{H_d}^2 + m_{H_u}^2.$$

The matrix $(\hat{m}_{\nu LL}^2)_K$ coincides with $(\hat{m}_{eLL}^2)_K$ and has the same evolution. For squarks we have introduced soft mass terms analogous to those previously discussed for sleptons. To estimate the corrections to the slepton masses induced by the renormalization group evolution we adopt the leading logarithmic approximation and substitute each of the running quantities with their initial conditions at the scale $\Lambda_L \approx \Lambda_f$ in eqs. (73). In particular, for the matrices $(\hat{m}_{(e,\nu)LL}^2)_K$, $(\hat{m}_{eRR}^2)_K$ and $\hat{A}_e$, these initial conditions are given in eqs. (65), (68) and (70), (71), respectively. In this approximation one easily sees that the largest corrections to the matrices $(\hat{m}_{(e,\nu)LL}^2)_K$ and $(\hat{m}_{eRR}^2)_K$ come from electroweak gauge interactions and are proportional to the identity matrix in flavour space. Due to the negative

⁹In the GUT normalization, such that $g_2 = g$ and $g_1 = \sqrt{5/3}g'$.

sign of the dominant contribution these diagonal elements increase by evolving the mass matrices from the cutoff scale down to the electroweak scale. This effect is taken into account in our numerical study presented in section 5.¹⁰ Each off-diagonal element of $(\hat{m}_{(e,\nu)LL}^2)_K$ receives at most a relative correction of order:

$$\frac{1}{16\pi^2} u \log\left(\frac{\Lambda_L}{m_{SUSY}}\right) \quad , \quad (74)$$

while those to $(\hat{m}_{eRR}^2)_K$ are even more suppressed, i.e.

$$\frac{1}{16\pi^2} u^2 \log\left(\frac{\Lambda_L}{m_{SUSY}}\right) \quad . \quad (75)$$

All such contributions can be safely neglected.

The matrix $\hat{A}_e$ gets a first correction by an overall multiplicative factor that can be absorbed, for instance, by a common rescaling of the parameters, and a second correction of the type $\hat{A}_e \rightarrow \hat{A}_e + K \hat{Y}_e$, which can be absorbed by the redefinition $z_f^{(\prime)} \rightarrow z_f^{(\prime)} + k y_f^{(\prime)}$, where K and k are constants. In our numerical study these effects are treated in this way. Finally, additional corrections to the off-diagonal elements of $\hat{A}_e$ are negligible. We can conclude that the corrections induced by the RG running are either negligible or could be absorbed in our parametrization. Thus, in our model the soft mass terms of sleptons are completely controlled by the flavour symmetry and by its spontaneous breaking. We recall that our model does not contain right-handed neutrinos and ignores the dynamics above the scale $\Lambda_L \approx \Lambda_f$. Notice that the Yukawa couplings of the charged leptons, $\hat{Y}_e$, remain diagonal during the evolution.

In a see-saw version, one should also include the effects of the running from the cutoff scale down to the right-handed neutrino mass scale(s) and the corresponding threshold effects. In this case the previous conclusions might change, since we expect for generic order one contributions from RG running that they enter the amplitudes of the branching ratios at the level of $1/(16\pi^2)$, due to the loop suppression, which is (roughly) equal to a contribution of order u^2 in the amplitude in our context.

4 Results in the mass insertion approximation

We can now evaluate the normalized branching ratios R_{ij} for the LFV transitions $\mu \rightarrow e\gamma$, $\tau \rightarrow \mu\gamma$ and $\tau \rightarrow e\gamma$. In this section we establish the leading dependence of the quantities R_{ij} on the symmetry breaking parameter u . We recall that in the class of models based on the flavour symmetry group $A_4 \times Z_3 \times U(1)_{FN}$ an estimate based on an effective Lagrangian approach suggests that R_{ij} generically scales as u^2 , which can be reconciled with the present bound on $R_{\mu e}$ only if the scale M of new physics is sufficiently large, above 10 TeV. The effective Lagrangian approach also indicates that, under certain conditions, in the SUSY case a cancellation might take place, and R_{ij} might scale as a combination of two terms, one proportional to u^4 and one proportional to $(m_j^2/m_i^2)u^2$, as shown in eq. (3), thus allowing for a substantially smaller scale of new physics, in the range of $(1 \div 10)$ TeV. When $R_{\mu e}$ is

¹⁰This effect can also be viewed as a redefinition of the initial parameters n_0 and $n_{1,2,3}^c$.

dominated by a one-loop amplitude with virtual particles of mass m_{SUSY} , M and m_{SUSY} are roughly related by $M = (4\pi/g)m_{SUSY}$ and a given lower bound on M corresponds to a lower bound on m_{SUSY} one order of magnitude smaller. Here we determine the actual leading order behaviour of R_{ij} by expressing the result as a power series in the parameter u .

4.1 Analytic results

In order to do so it is useful to first analyse the predictions in the so-called mass insertion (MI) approximation, where we have a full control of the results in its analytic form. A more complete discussion based on one-loop results can be found in section 5. For the case at hand, the MI approximation consists in expanding the amplitudes in powers of the off-diagonal elements of the slepton mass matrices, normalized to their average mass. From the expression of the mass matrices of the previous section we see that in our case such an expansion amounts to an expansion in the parameters u and t , which we can directly compare with eq. (3). A common value in the diagonal entries of both LL and RR blocks is assumed and we consequently set $n_0 = n_1^c = n_2^c = n_3^c = 1$ and also $\hat{n}_1 = \hat{n}_2 = 0$ in this section, so that the average mass becomes m_{SUSY} . On the contrary, no assumptions have been made for the trilinear soft terms, which keep the expression as in eqs. (70-72). Concerning chargino and neutralino mass matrices, they carry a dependence on the vector boson masses $m_{W,Z}$ through off-diagonal matrix elements. Such a dependence is not neglected in this approximation, but only the leading order term of an expansion in $m_{W,Z}$ over the relevant SUSY mass combination is kept. At the same time, to be consistent, we have to neglect the supersymmetric contributions of $\hat{m}_{\nu LL}^2$ and $\hat{m}_{e LL}^2$ and therefore $\hat{m}_{\nu LL}^2$ and $\hat{m}_{e LL}^2$ coincide. Using these simplifications, the ratios R_{ij} can be expressed as:

$$R_{ij} = \frac{48\pi^3\alpha}{G_F^2 m_{SUSY}^4} (|A_L^{ij}|^2 + |A_R^{ij}|^2) \quad . \quad (76)$$

At the LO, the amplitudes A_L^{ij} and A_R^{ij} are given by:

$$\begin{aligned} A_L^{ij} &= a_{LL}(\delta_{ij})_{LL} + a_{RL} \frac{m_{SUSY}}{m_i} (\delta_{ij})_{RL} \\ A_R^{ij} &= a_{RR}(\delta_{ij})_{RR} + a_{LR} \frac{m_{SUSY}}{m_i} (\delta_{ij})_{LR} \end{aligned} \quad (77)$$

where $a_{CC'}$ ($C, C' = L, R$) are dimensionless functions of the ratios $M_{1,2}/m_{SUSY}$, μ/m_{SUSY} and of $\tan\theta_W$. Their typical size is one tenth of $g^2/(16\pi^2)$, g being the $SU(2)_L$ gauge

coupling constant. In our conventions their explicit expression is given by:

$$\begin{aligned}
a_{LL} &= \frac{g^2}{16\pi^2} \left[f_{1n}(a_2) + f_{1c}(a_2) + \frac{M_2\mu \tan \beta}{M_2^2 - \mu^2} (f_{2n}(a_2, b) + f_{2c}(a_2, b)) \right. \\
&\quad \left. + \tan^2 \theta_W \left(f_{1n}(a_1) - \frac{M_1\mu \tan \beta}{M_1^2 - \mu^2} f_{2n}(a_1, b) - M_1 \left(\left(\frac{z_i}{y_i} + \zeta \right) m_{SUSY} - \mu \tan \beta \right) \frac{f_{3n}(a_1)}{m_{SUSY}^2} \right) \right] \\
a_{RL} &= \frac{g^2}{16\pi^2} \tan^2 \theta_W \frac{M_1}{m_{SUSY}} 2f_{2n}(a_1) \\
a_{RR} &= \frac{g^2}{16\pi^2} \tan^2 \theta_W \left[4f_{1n}(a_1) + 2 \frac{M_1\mu \tan \beta}{M_1^2 - \mu^2} f_{2n}(a_1, b) - M_1 \left(\left(\frac{z_i}{y_i} + \zeta \right) m_{SUSY} - \mu \tan \beta \right) \frac{f_{3n}(a_1)}{m_{SUSY}^2} \right] \\
a_{LR} &= \frac{g^2}{16\pi^2} \tan^2 \theta_W \frac{M_1}{m_{SUSY}} 2f_{2n}(a_1)
\end{aligned} \tag{78}$$

where $a_{1,2} = M_{1,2}^2/m_{SUSY}^2$, $b = \mu^2/m_{SUSY}^2$ and $f_{i(c,n)}(x, y) = f_{i(c,n)}(x) - f_{i(c,n)}(y)$. The functions $f_{in}(x)$ and $f_{ic}(x)$, slightly different from those in [26], are given by:

$$\begin{aligned}
f_{1n}(x) &= (-17x^3 + 9x^2 + 9x - 1 + 6x^2(x+3) \log x)/(24(1-x)^5) \\
f_{2n}(x) &= (-5x^2 + 4x + 1 + 2x(x+2) \log x)/(4(1-x)^4) \\
f_{3n}(x) &= (1 + 9x - 9x^2 - x^3 + 6x(x+1) \log x)/(2(1-x)^5) \\
f_{1c}(x) &= (-x^3 - 9x^2 + 9x + 1 + 6x(x+1) \log x)/(6(1-x)^5) \\
f_{2c}(x) &= (-x^2 - 4x + 5 + 2(2x+1) \log x)/(2(1-x)^4)
\end{aligned} \tag{79}$$

Notice that $a_{CC'}$ do neither depend on u nor on the fermion masses $m_{i,j}$. Finally, $(\delta_{ij})_{CC'}$

ij	w_{ij}^{LL}	w_{ij}^{RL}	w_{ij}^{RR}	w_{ij}^{LR}
μe	$\hat{n}_4$	$\zeta(c_F - c)$	0	$2 \frac{(z_e y_\mu - z_\mu y_e)}{y_e y_\mu} c + \zeta(c_F - c)$
τe	$\hat{n}_5$	$\zeta(c_F - c)$	0	$2 \frac{(z_e y_\tau - z_\tau y_e)}{y_e y_\tau} c + \zeta(c_F - c)$
$\tau \mu$	$\hat{n}_6$	$\zeta(c_F - c)$	0	$2 \frac{(z_\mu y_\tau - z_\tau y_\mu)}{y_\mu y_\tau} c + \zeta(c_F - c)$

Table 2: Coefficients $w_{ij}^{CC'}$ characterizing the transition amplitudes for $\mu \rightarrow e\gamma$, $\tau \rightarrow e\gamma$ and $\tau \rightarrow \mu\gamma$, in the MI approximation in which n_0 and n_i^c are set to one and $\hat{n}_{1,2}$ to zero so that w_{ij}^{RR} vanish.

parametrize the MIs and are defined as:

$$(\delta_{ij})_{CC'} = \frac{(\hat{m}_{eCC'}^2)_{ij}}{m_{SUSY}^2} . \tag{80}$$

From the mass matrices of the previous section, we find ($j < i$):

$$\begin{aligned}
(\delta_{ij})_{LL} &= w_{ij}^{LL} u^2 \quad , \quad (\delta_{ij})_{RL} = \frac{m_i}{m_{SUSY}} \left(w_{ij}^{RL} u + w_{ij}'^{RL} u^2 \right) \\
(\delta_{ij})_{RR} &= w_{ij}^{RR} \frac{m_j}{m_i} u \quad , \quad (\delta_{ij})_{LR} = w_{ij}^{LR} \frac{m_j}{m_{SUSY}} u
\end{aligned} \tag{81}$$

where for the mass insertion $(\delta_{ij})_{RL}$ we have also displayed the NLO contributions, in order to better compare our results with those of the effective Lagrangian approach. The explicit expression for the LO coefficients $w_{ij}^{CC'}$ are listed in table 2. Also the NLO coefficients $w_{ij}^{'RL}$ are dimensionless combinations of order one parameters. By substituting the mass insertions of eq. (81) into the amplitudes $A_{L,R}^{ij}$ of eq. (77) and by using eq. (76), we get:

$$R_{ij}^{SUSY} = \frac{48\pi^3\alpha}{G_F^2 M^4} \left[|w_{ij}^{(0)} u|^2 + 2w_{ij}^{(0)} w_{ij}^{(1)} u^3 + |w_{ij}^{(1)} u^2|^2 + \frac{m_j^2}{m_i^2} |w_{ij}^{(2)} u|^2 \right] \quad (82)$$

with $M = (4\pi/g)m_{SUSY}$ and

$$\begin{aligned} w_{ij}^{(0)} &= \frac{16\pi^2}{g^2} a_{RL} w_{ij}^{RL} \quad , \\ w_{ij}^{(1)} &= \frac{16\pi^2}{g^2} \left(a_{LL} w_{ij}^{LL} + a_{RL} w_{ij}^{'RL} \right) \quad , \\ w_{ij}^{(2)} &= \frac{16\pi^2}{g^2} \left(a_{RR} w_{ij}^{RR} + a_{LR} w_{ij}^{LR} \right) \quad . \end{aligned} \quad (83)$$

The behaviour displayed in eq. (82) differs from the one expected on the basis of the effective Lagrangian approach in the SUSY case, eq. (3). This is due to the presence of the term $w_{ij}^{(0)} \propto w_{ij}^{RL}$. Assuming $w_{ij}^{RL} = 0$ we recover what is expected from the effective Lagrangian approach in the SUSY case, whereas when w_{ij}^{RL} does not vanish, the LO behaviour matches the prediction of the effective Lagrangian approach in the generic, non-supersymmetric case, eq. (2). As shown in table 2, the coefficient w_{ij}^{RL} is universal, namely it is independent from the flavour indices and it vanishes in two cases:

- i) $c_F = c$, which reflects the alignment of the VEVs of the scalar and auxiliary components of the flavon supermultiplet φ_T , see eqs. (9) and (21).
- ii) $\zeta = 0$ which can be realized by special choices of the soft SUSY breaking terms in the flavon sector, i.e. the assumption of universal soft SUSY breaking terms in the flavon potential.

In our model none of these possibilities is natural, see [16], and both require a tuning of the underlying parameters. If $w_{ij}^{RL} = 0$, the result expected from the effective Lagrangian approach in the SUSY case is obtained in a non-trivial way. Indeed, it is a consequence of a cancellation taking place when going from the Lagrangian to the physical basis. In particular, for $w_{ij}^{RL} = 0$ the MI $(\delta_{ij})_{RL}$ scales as $m_i u^2 / m_{SUSY}$ and not as $m_i u / m_{SUSY}$ as we might naively guess by looking at eq. (60). As a consequence R_{ij}^{SUSY} scales as u^4 and not as u^2 for $m_j = 0$.

In the general case when w_{ij}^{RL} is non-vanishing, the dominant contribution to R_{ij}^{SUSY} regarding the expansion in u is flavour independent and, at the LO in the u expansion, we predict $R_{\mu e} = R_{\tau \mu} = R_{\tau e}$, at variance with the predictions of most of the other models, where, for instance, $R_{\mu e} / R_{\tau \mu}$ can be much smaller than one [1, 27, 28]. If w_{ij}^{RL} is non-vanishing, it is interesting to analyze the relative weight of the leading and sub-leading contributions to R_{ij} . For this purpose we list in table 3 the expressions and the numerical values of the functions $a_{CC'}$, in the limit $\mu = M_{1,2} = m_{SUSY}$. As one can see, in this limit

a_{LL}	$\frac{1}{240} \frac{g^2}{16\pi^2} \left[1 - 3 \left(1 + 4 \left(\frac{z_i}{y_i} + \zeta \right) \right) \tan^2 \theta_W + 4 \left(4 + 5 \tan^2 \theta_W \right) \tan \beta \right]$	$+(2.0 \div 16.3)$
$a_{RL} = a_{LR}$	$\frac{1}{12} \frac{g^2}{16\pi^2} \tan^2 \theta_W$	0.30
a_{RR}	$\frac{1}{60} \frac{g^2}{16\pi^2} \tan^2 \theta_W \left[-3 - 3 \left(\frac{z_i}{y_i} + \zeta \right) - \tan \beta \right]$	$-(0.5 \div 1.3)$

Table 3: Coefficients $a_{CC'}$ characterizing the transition amplitudes for $\mu \rightarrow e\gamma$, $\tau \rightarrow e\gamma$ and $\tau \rightarrow \mu\gamma$, in the MI approximation in which n_0 and n_i^c are set to one and $\hat{n}_{1,2}$ to zero and by taking the limit $\mu = M_{1,2} = m_{SUSY}$. Numerical values are given in units of $g^2/(192\pi^2)$ and using $\sin^2 \theta_W = 0.23$, $(z_i/y_i + \zeta) = 1$, and $\tan \beta = 2 \div 15$.

the dominant coefficient is a_{LL} , which is larger than $a_{RL} = a_{LR}$ by a factor $7 \div 54$, and larger than a_{RR} by a factor $-(4 \div 13)$, depending on $\tan \beta = 2 \div 15$. Assuming coefficients $w_{ij}^{CC'}$ of order one in eqs. (83), we see that the most important contributions in the amplitudes for the considered processes are $a_{RL}u$ and $a_{LL}u^2$. The ratio between the sub-leading and the leading one is $(a_{LL}/a_{RL})u \approx (7 \div 54)u$. When u is close to its lower bound, which in our model requires a small value of $\tan \beta$, the leading contribution clearly dominates over the sub-leading one. However, for u close to 0.05, which allows to consider larger values of $\tan \beta \approx 15$, the non-leading contribution can be as large as the leading one and can even dominate over it. The transition between the two regimes occurs towards larger values of u .

The numerical dominance of the coefficient a_{LL} has also another consequence: for vanishing w_{ij}^{RL} , R_{ij} is dominated by the contributions of $a_{LL}w_{ij}^{LL}$, whose values are not universal, but expected to be of the same order of magnitude for all channels. Thus even when $w_{ij}^{RL} = 0$, we predict $R_{\mu e} \approx R_{\tau\mu} \approx R_{\tau e}$. Even if to illustrate our results explicitly we have taken the special limit $\mu = M_{1,2} = m_{SUSY}$, a numerical study confirms that they remain approximately correct when more generic regions of the parameter space of the model are considered.

4.2 Failure of the effective Lagrangian approach

Why the results of the effective Lagrangian approach in the SUSY case do not apply in the model under consideration? It is worth to summarize the main assumptions underlying the effective Lagrangian approach in the SUSY case in [4]:

1. The only sources of chirality flip are either fermion masses or sfermion masses of RL-type.

2. Both, fermion masses and sfermion masses of RL-type, up to the order u^2 , are dominated by the insertions of φ_T or φ_T^2 in the relevant operators.

As a consequence also the operators describing dipole transitions, which have the same chiral structure as the charged lepton mass terms, are dominated by the insertions of φ_T or φ_T^2 , up to the order u^2 . For instance one such operator is:

$$\frac{e}{m_{SUSY}^2} \frac{\theta_{FN}^2}{\Lambda_f^2} e^c H_d \sigma_{\mu\nu} F^{\mu\nu} \left(\frac{\varphi_T}{\Lambda_f} l \right) + \dots \quad (84)$$

and similarly for μ^c and τ^c . Dots denote additional contributions such as those coming from the insertion of φ_T^2 . Here e is the electric charge.

Indeed, in our model condition 2 is violated. The explicit SUSY model considered here contains another set of fields which was not present in the effective Lagrangian framework, namely the driving fields φ_0^T . The driving fields represent an important ingredient of our model, since they are directly responsible for the vacuum alignment of the flavon fields. In the effective Lagrangian approach the alignment was postulated, without referring to a specific dynamical mechanism to generate it, and the driving fields were not included among the relevant degrees of freedom. In our model φ_0^T has no direct coupling to matter fields. Such a coupling arises indirectly through the mediation of the flavon φ_T , which is coupled to matter via interactions suppressed by $1/\Lambda_f$ and to φ_0^T via interactions proportional to e.g. a large scale M_T :

$$w = x_e \frac{\theta_{FN}^2}{\Lambda_f^2} e^c H_d \left(\frac{\varphi_T}{\Lambda_f} l \right) + M_T (\varphi_0^T \varphi_T) + \dots \quad (85)$$

M_T is a mass scale of the order of the VEV of φ_T , $M_T \approx u \Lambda_f$ and dots denote further contributions. It can be shown that the VEV of φ_0^T is proportional to m_{SUSY} [16]. When the auxiliary fields of φ_T are eliminated slepton masses of RL-type receive a contribution from the insertion of $\bar{\varphi}_0^T$:

$$y_e \frac{\theta_{FN}^2}{\Lambda_f^2} \tilde{e}^c H_d \left(M_T \frac{\bar{\varphi}_0^T}{\Lambda_f} \tilde{l} \right) + \dots \quad (86)$$

Similar terms for $\tilde{\mu}^c$ and $\tilde{\tau}^c$ are also present. Therefore dipole operators with the same type of insertions are expected in the low-energy limit. Up to loop factors:

$$\frac{e}{m_{SUSY}^3} \frac{\theta_{FN}^2}{\Lambda_f^2} e^c H_d \sigma_{\mu\nu} F^{\mu\nu} \left(M_T \frac{\bar{\varphi}_0^T}{\Lambda_f} l \right) + \dots \quad (87)$$

Since φ_0^T has a dominant VEV of order m_{SUSY} and $M_T/\Lambda_f \approx u$, this operator is similar in size to the operator of eq. (84). A similar contribution arises, if the coupling of two flavons φ_T to the driving field φ_0^T is taken into account instead of the term $M_T(\varphi_0^T \varphi_T)$. Operators of this type were not included in the effective Lagrangian approach, simply because the driving field φ_0^T was absent. The set of operators of type as in eq. (87) and eq. (84) are aligned in flavour space only to the LO. At the NLO such an alignment fails and this produces a non-vanishing term w_{ij}^{RL} . Notice that the insertion of φ_0^T both in the slepton mass and in the dipole operators occurs through a combination of the type $M_T \bar{\varphi}_0^T / \Lambda_f$. If

we did not account for the large coupling of order M_T , the mere insertion of $\bar{\varphi}_0^T/\Lambda_f$ in the mass and in the dipole operators would largely underestimate the effect. It would be interesting to investigate the low-energy structure of dipole operators in a complete SUSY model in which the driving fields are absent and the alignment of flavon vacua is realized via some alternative mechanism. This would allow to verify whether the failure of the effective Lagrangian approach is entirely due to the presence of the driving fields or other subtleties occur when performing the low-energy limit.

5 Numerical analysis

In this section we perform a numerical study of the normalized branching ratios R_{ij} and of the deviation δa_μ of the anomalous magnetic moment of the muon from the SM value. We use the full one-loop results for the branching ratios of the radiative decays as well as for δa_μ . These can be found in [29–32] and are displayed in appendix C for convenience.

5.1 Framework

As discussed in the preceding sections, in our model the flavour symmetry $A_4 \times Z_3 \times U(1)_{FN} \times U(1)_R$ constrains not only the mass matrices of leptons, but also those of sfermions. These are given at the high energy scale $\Lambda_f \approx \Lambda_L$, which we assume to be close to 10^{16} GeV, the SUSY grand unification scale. The flavour symmetry does not fix the soft SUSY mass scale m_{SUSY} . It also does not constrain the parameters involved in the gaugino as well as the Higgs(ino) sector. These are fixed by our choice of a SUGRA framework in which m_{SUSY} is the common soft mass scale for all scalar particles (in the literature usually denoted as m_0) and $m_{1/2}$ the common mass scale of the gauginos. Thus, at the scale $\Lambda_f \approx \Lambda_L$ we have ¹¹

$$M_1(\Lambda_L) = M_2(\Lambda_L) = m_{1/2} . \quad (88)$$

Effects of RG running lead at low energies (at the scale m_W of the W mass) to the following masses for gauginos

$$M_1(m_W) \simeq \frac{\alpha_1(m_W)}{\alpha_1(\Lambda_L)} M_1(\Lambda_L) \quad M_2(m_W) \simeq \frac{\alpha_2(m_W)}{\alpha_2(\Lambda_L)} M_2(\Lambda_L) , \quad (89)$$

where $\alpha_i = g_i^2/4\pi$ ($i = 1, 2$) and according to gauge coupling unification at $\Lambda_f \approx \Lambda_L$, $\alpha_1(\Lambda_L) = \alpha_2(\Lambda_L) \simeq 1/25$. Concerning the effects of the RG running on the soft mass terms, as we have seen in section 3.2 these are small or can be absorbed into our parametrization of the soft mass terms. Thus, in the contributions $(\hat{m}_{eRL}^2)_{1,2}$ to the RL block we take m_{SUSY} as input parameter. Nevertheless, we explicitly take into account the RG effect on the average mass scale of the LL block, m_L^2 , and in the RR block, m_R^2 ,

$$\begin{aligned} m_L^2(m_W) &\simeq m_L^2(\Lambda_L) + 0.5M_2^2(\Lambda_L) + 0.04M_1^2(\Lambda_L) \simeq m_{SUSY}^2 + 0.54m_{1/2}^2 , \\ m_R^2(m_W) &\simeq m_R^2(\Lambda_L) + 0.15M_1^2(\Lambda_L) \simeq m_{SUSY}^2 + 0.15m_{1/2}^2 . \end{aligned} \quad (90)$$

¹¹The gluino mass parameter M_3 is not relevant in our analysis.

The parameter μ is fixed through the requirement of correct electroweak symmetry breaking

$$|\mu|^2 = \frac{m_{H_d}^2 - m_{H_u}^2 \tan^2 \beta}{\tan^2 \beta - 1} - \frac{1}{2} m_Z^2. \quad (91)$$

Since in the SUGRA framework the soft Higgs mass parameters are also given by m_{SUSY} at the high energy scale, $m_{H_u}^2(\Lambda_L) = m_{H_d}^2(\Lambda_L) = m_{SUSY}^2$, the relation in eq. (91) reads at low energies

$$|\mu|^2 \simeq -\frac{m_Z^2}{2} + m_{SUSY}^2 \frac{1 + 0.5 \tan^2 \beta}{\tan^2 \beta - 1} + m_{1/2}^2 \frac{0.5 + 3.5 \tan^2 \beta}{\tan^2 \beta - 1}, \quad (92)$$

so that μ is determined by m_{SUSY} , $m_{1/2}$ and $\tan \beta$ up to its sign. We recall that in our model the low energy parameter $\tan \beta$ is related to the size of the expansion parameter u , the mass of the τ lepton and the τ Yukawa coupling y_τ , as shown in eq. (18). For this reason, requiring $1/3 \lesssim |y_\tau| \lesssim 3$ constrains $\tan \beta$ to lie in the range $2 \lesssim \tan \beta \lesssim 15$. As already commented, the lower bound $\tan \beta = 2$ is almost excluded experimentally, since such low values of $\tan \beta$ usually lead to a mass for the lightest Higgs below the LEP2 bound of 114.4 GeV [33].¹²

In our numerical analysis the parameters are the following: the two independent mass scales m_{SUSY} and $m_{1/2}$, the sign of the parameter μ and the parameters of the slepton mass matrices shown in section 3.1 in the physical basis. We recall that the results of section 3.1 have been obtained under the assumption that the parameters are real and we keep working under the same assumption here. We also assume that the parameters on the diagonal of the slepton mass matrices $(\hat{m}_{(e,\nu)LL}^2)_K$ and $(\hat{m}_{eRR}^2)_K$, n_0 and $n_{1,2,3}^c$, are positive in order to favour positive definite square-masses, to avoid electric-charge breaking minima and further sources of electroweak symmetry breaking. The absolute value of the $\mathcal{O}(1)$ parameters is varied between $1/2$ and 2 . We will chose some representative values for u in the allowed range $0.007 \lesssim u \lesssim 0.05$. The other expansion parameter t is fixed to be 0.05 . In the analysis of the normalized branching ratios R_{ij} we fix $\tan \beta$ and u and then we derive the Yukawa couplings y_e , y_μ and y_τ . When discussing the anomalous magnetic moment of the muon instead we vary y_τ between $1/3$ and 3 and calculate $\tan \beta$ by using eq. (18). Having determined $\tan \beta$, the Yukawa couplings y_e and y_μ can be computed.

The allowed region of the parameter space is determined by performing several tests. We check whether the mass of the lightest chargino is above 100 GeV [18], whether the lightest neutralino is lighter than the lightest charged slepton, whether the lower bounds for the charged slepton masses are obeyed [18] and whether the masses of all sleptons are positive. The constraint on the mass of the lightest chargino implies a lower bound on $m_{1/2}$ which slightly depends on the sign of μ . In our plots for R_{ij} we also show the results for points of the parameter space that do not respect the chargino mass bound. For low values of m_{SUSY} , e.g. $m_{SUSY} = 100$ GeV, the requirement that the lightest neutralino is lighter than the lightest charged slepton is equivalent to the requirement that the parameters in the diagonal entries of the slepton mass matrices $(\hat{m}_{(e,\nu)LL}^2)_K$ and $(\hat{m}_{eRR}^2)_K$ are larger than one. For larger values of m_{SUSY} , e.g. $m_{SUSY} = 1000$ GeV, this requirement does not affect

¹²This bound assumes that the Higgs is SM-like. For the case of generic MSSM Higgs the bound is much lower, 91.0 GeV [34].

our analysis anymore. We note that masses of charginos and neutralinos are essentially independent from the $\mathcal{O}(1)$ parameters of the slepton mass matrices and thus their masses fulfill with very good accuracy (better for larger $m_{1/2}$)

$$M_{\tilde{\chi}_1^0} \approx 0.4m_{1/2}, M_{\tilde{\chi}_2^0} \approx M_{\tilde{\chi}_1^-} \approx 0.8m_{1/2}, M_{\tilde{\chi}_3^0} \approx M_{\tilde{\chi}_4^0} \approx M_{\tilde{\chi}_2^-} \approx |\mu|. \quad (93)$$

For the slepton masses we find certain ranges which depend on our choice of the $\mathcal{O}(1)$ parameters.

5.2 Results for radiative leptonic decays

We first discuss the results for the branching ratio of the decay $\mu \rightarrow e\gamma$. This branching ratio is severely constrained by the result of the MEGA experiment [35]

$$R_{\mu e} \approx BR(\mu \rightarrow e\gamma) < 1.2 \times 10^{-11} \quad (94)$$

and will be even more constrained by the on-going MEG experiment [36] which will probe the regime

$$R_{\mu e} \approx BR(\mu \rightarrow e\gamma) \gtrsim 10^{-13}. \quad (95)$$

We explore the parameter space of the model by considering two different values of the expansion parameter u , $u = 0.01$ and $u = 0.05$, two different values of $\tan \beta$, $\tan \beta = 2$ and $\tan \beta = 15$, as well as two different values of the mass scale m_{SUSY} , $m_{SUSY} = 100$ GeV and $m_{SUSY} = 1000$ GeV. We show our results in scatter plots in Figure 1 choosing $m_{1/2}$ to be $m_{1/2} \lesssim 1000$ GeV. All plots shown in Figure 1 are generated for $\mu > 0$.

As one can see from Figure 1(a), for very low $\tan \beta = 2$, small $u = 0.01$, small $m_{SUSY} = 100$ GeV the experimental upper limit from the MEGA experiment on $BR(\mu \rightarrow e\gamma)$ can be passed in almost all parameter space of our model for values of $m_{1/2}$ as small as 450 GeV. For $m_{SUSY} = 100$ GeV and $m_{1/2} = 450$ GeV the sparticle masses are rather light: the lightest neutralino has a mass of 175 GeV, the lightest chargino of 350 GeV, the masses of the right-handed (charged) sleptons vary between 175 and 285 GeV and the masses of the left-handed sleptons are in the range $(250 \div 500)$ GeV. Thus, especially the right-handed sleptons are expected to be detected at LHC. In a model also including quarks (and hence squarks) we find for the squarks that they can have masses $\gtrsim 700$ GeV and gluinos with masses of about 1000 GeV, all accessible at LHC. To pass the prospective bound coming from the MEG experiment in a sizable portion of parameter space of our model $m_{1/2}$ has to be chosen larger, $m_{1/2} \gtrsim 600$ GeV. Then, however, the masses of the sleptons might only be detected at LHC in case of right-handed sleptons. As one can see, values of $m_{1/2} \lesssim 155$ GeV are excluded due to the constraint on the lightest chargino mass. Studying the same value of $\tan \beta$ and u , but taking m_{SUSY} to be as large as 1000 GeV, we can see from Figure 1(b) that now the bound set by the MEGA experiment on $BR(\mu \rightarrow e\gamma)$ is respected in the whole parameter space of our model for all values of $m_{1/2}$. Also the foreseen limit of the MEG experiment can only exclude a smaller part of the parameter space of the model for all values of $m_{1/2}$. In this setup, the prospects for detecting SUSY particles at LHC are the best for gauginos due to the possible low value of $m_{1/2}$. The slepton masses are expected to be roughly m_{SUSY} and thus too large to allow for a detection at LHC.

Increasing the value of the expansion parameter u from $u = 0.01$ to $u = 0.05$, as done in Figure 1(c) and 1(d), increases also the branching ratio of the decay $\mu \rightarrow e\gamma$ by approximately two orders of magnitude, since the different contributions to the branching ratio scale at least with u^2 , as analyzed in section 4. For this reason for low values of $m_{SUSY} = 100$ GeV, $m_{1/2}$ has to take values $m_{1/2} \gtrsim 600$ GeV in order for the result of $BR(\mu \rightarrow e\gamma)$ to be compatible with the MEGA bound at least in some portion of the parameter space of our model. For the point $(m_{SUSY}, m_{1/2}) = (100 \text{ GeV}, 600 \text{ GeV})$ the sparticle spectrum is characterized as follows: the lightest neutralino has a mass of 240 GeV, the lightest chargino of 470 GeV, right-handed sleptons between 250 and 350 GeV and left-handed sleptons generally above 300 GeV. For this reason there still exists the possibility to detect right-handed sleptons at LHC. Concerning gluinos and squarks these are expected to have masses between 1000 and 1500 GeV so that they also can be detected at LHC. As one can see from Figure 1(c) the on-going MEG experiment can probe nearly the whole parameter space of the model for $\tan\beta = 2$, $u = 0.05$ and $m_{SUSY} = 100$ GeV for values of $m_{1/2} \lesssim 1000$ GeV. Increasing the parameter m_{SUSY} to 1000 GeV shows that applying the existing bound on $BR(\mu \rightarrow e\gamma)$ of 1.2×10^{-11} cannot exclude small values of $m_{1/2}$. The situation changes, if the expected bound from the MEG experiment is employed, because then values of $m_{1/2}$ smaller than 1000 GeV become disfavoured.

Finally, we show in Figure 1(e) and 1(f) the results obtained for $\tan\beta = 15$. We remind that this value is the largest possible one of $\tan\beta$ in our model. Requiring that the τ Yukawa coupling does not become too large entails that $\tan\beta = 15$ fixes the expansion parameter u to take a value close to its upper limit, $u = 0.05$. The value of $BR(\mu \rightarrow e\gamma)$ is thus enhanced through $\tan\beta$ as well as u . This is clearly shown in Figure 1(e) and 1(f), because for a low value of $m_{SUSY} = 100$ GeV already the MEGA bound practically excludes almost the whole parameter space of our model for all values of $m_{1/2} \lesssim 1000$ GeV. Increasing the mass parameter m_{SUSY} to 1000 GeV slightly improves the situation, because now there exists a marginal probability to pass the MEGA bound. Again, however, the MEG experiment can probe all parameter space of our model for $m_{1/2} \lesssim 1000$ GeV. Thus, for $m_{SUSY} \lesssim 1000$ GeV and $m_{1/2} \lesssim 1000$ GeV the parameter space of our model is already severely constrained for moderate values of $\tan\beta$ which entail large $u \approx 0.05$ by the bound coming from the MEGA collaboration, but surely will be conclusively probed by the MEG experiment. Choosing $\mu < 0$ hardly affects the results presented here apart from slightly decreasing the lower bound on $m_{1/2}$ coming from the chargino mass bound. Thus, all statements made also apply for $\mu < 0$.

In summary, the current bound on $BR(\mu \rightarrow e\gamma)$ prefers regions in the parameter space of our model with small u or small $\tan\beta$, as long as the SUGRA mass parameters should be chosen smaller than 1000 GeV. The foreseen MEG bound strongly favours regions in which u is small for m_{SUSY} and $m_{1/2}$ being not too large. The fact that smaller values of u are preferred has consequences also for the expectations of the detection prospects for the reactor mixing angle θ_{13} , because this angle scales with u : it might thus not be possible to detect θ_{13} with the reactor and neutrino beam experiments under preparation [37, 38].

Concerning the radiative τ decays, $\tau \rightarrow \mu\gamma$ and $\tau \rightarrow e\gamma$, the result found in the MI approximation that the branching ratios of these decays are of the same order of

(a) $\tan \beta = 2$, $u = 0.01$ and $m_{SUSY} = 100$ GeV.

(b) $\tan \beta = 2$, $u = 0.01$ and $m_{SUSY} = 1000$ GeV.

(c) $\tan \beta = 2$, $u = 0.05$ and $m_{SUSY} = 100$ GeV.

(d) $\tan \beta = 2$, $u = 0.05$ and $m_{SUSY} = 1000$ GeV.

(e) $\tan \beta = 15$, $u = 0.05$ and $m_{SUSY} = 100$ GeV.

(f) $\tan \beta = 15$, $u = 0.05$ and $m_{SUSY} = 1000$ GeV.

Figure 1: Scatter plots of $BR(\mu \rightarrow e\gamma)$ as a function of $m_{1/2}$, for different values of $\tan \beta$, u and m_{SUSY} . The red (dark gray) points correspond to points in which the mass of the lightest chargino is below the limit coming from direct searches. The horizontal lines show the current MEGA bound (continuous line) and the prospective MEG bound (dashed line).

magnitude as $BR(\mu \rightarrow e\gamma)$ is essentially confirmed in a numerical analysis. Due to the random parameters differences up to two orders of magnitude are expected and found, especially for the case of larger $\tan \beta$. However, it is still highly improbable that the

decays $\tau \rightarrow \mu\gamma$ and $\tau \rightarrow e\gamma$ could be detected at a SuperB factory, assuming a prospective limit of $BR(\tau \rightarrow \mu\gamma), BR(\tau \rightarrow e\gamma) \gtrsim 10^{-9}$ [39].

5.3 Results for anomalous magnetic moment of the muon

As is well known, the value found for the anomalous magnetic moment of the muon [40]

$$a_\mu^{EXP} = 116592080(63) \times 10^{-11} \quad (96)$$

shows a 3.4σ deviation

$$\delta a_\mu = a_\mu^{EXP} - a_\mu^{SM} = +302(88) \times 10^{-11} \quad (97)$$

from the value expected in the SM [41]

$$a_\mu^{SM} = 116591778(61) \times 10^{-11} . \quad (98)$$

Similar discrepancies have been reported in [42]. Thus, it might be interesting to consider the case in which this deviation is attributed to the presence of SUSY particles with masses of a few hundred GeV. The one-loop contribution to the anomalous magnetic moment of the muon in supersymmetric extensions of the SM has been studied by several authors [29]. We

Figure 2: Scatter plots in the plane $BR(\mu \rightarrow e\gamma) - \delta a_\mu$, for values of $u = 0.01, 0.05$. The value of $\tan \beta$ is fixed through the relation with the τ Yukawa coupling, which lies in the interval $[1/3, 3]$. The values of m_{SUSY} and of $m_{1/2}$ are chosen between 10 and 300 GeV for the left panel and between 10 and 1000 GeV in the right one. The horizontal lines correspond to the MEGA (continuous line) and the MEG bounds (dashed line); the vertical lines correspond to the measurements on δa_μ : the continuous one is the best fit value and the dashed ones correspond to the 3σ boundaries.

study the compatibility between the requirement that δa_μ is explained by the exchange of relatively light SUSY particles and the experimental upper limit on $BR(\mu \rightarrow e\gamma)$ coming from the MEGA experiment. We choose again two different values of u , $u = 0.01$ and $u = 0.05$. To better explore the parameter space we vary the τ Yukawa coupling between $1/3$ and 3 and fix the value of $\tan \beta$ through the relation given in eq. (18). As a consequence in the plot for $u = 0.01$, see Figure 2(a), $2 \lesssim \tan \beta \lesssim 3$ holds and for $u = 0.05$ $\tan \beta$

takes values $2 \lesssim \tan \beta \lesssim 15$. Similarly, m_{SUSY} and $m_{1/2}$ are chosen to lie in intervals $[10 \text{ GeV}, 300 \text{ GeV}]$ and $[10 \text{ GeV}, 1000 \text{ GeV}]$ for $u = 0.01$ and $u = 0.05$, respectively. The different choice of intervals is due to the fact that values of a few hundred GeV for m_{SUSY} and $m_{1/2}$ are disfavoured by the existing limit on $BR(\mu \rightarrow e\gamma)$ when $u = 0.05$. As one can clearly see from Figure 2, in almost the whole parameter space of our model it is not natural to reproduce the observed deviation of the muon anomalous magnetic moment and at the same time to respect the existing bound on the branching ratio of $\mu \rightarrow e\gamma$.

This kind of incompatibility is well known in supersymmetric theories, because the explanation of the 3.4σ discrepancy necessitates small values of m_{SUSY} and $m_{1/2}$ and larger values of $\tan \beta$, which in turn enhance the branching ratio of the radiative LFV decays. Thus, we have to conclude that either there exist further sources of contributions to the anomalous magnetic moment of the muon beyond those present in our model, or - as is also discussed in the literature - the theoretical value a_μ^{SM} found in the SM is closer to a_μ^{EXP} so that the eventual discrepancy becomes less than 100×10^{-11} , a value which could well be explained in our model.

6 Conclusion

While awaiting the start of LHC and the first exploration of the TeV scale, the solution to the hierarchy problem offered by SUSY still represents a very appealing option, with several interesting consequences, such as a successful gauge coupling unification, a viable particle candidate for dark matter and a possible explanation of the observed discrepancy in the anomalous magnetic moment of the muon. Nevertheless the existence of new states carrying flavour indices at the TeV scale is a serious problem in model building, given the success of the SM in describing all known phenomena involving flavour transitions. The lepton sector makes no exception. The flavour conversion observed in neutrino oscillations might be related to potentially large effects in rare decays of the charged leptons. A naive dimensional estimate of these effects, assuming new physics at the TeV scale, requires a large suppression in the relevant amplitudes, to pass the existing bounds. A possible explanation for such a suppression is the presence of a flavour symmetry, which is independently motivated by the hierarchy in the charged lepton mass spectrum and by the nearly TB mixing pattern of the lepton mixing matrix. Here we have considered a SUSY model invariant under the flavour symmetry group $A_4 \times Z_3 \times U(1)_{FN}$, originally proposed in order to describe lepton masses and mixing angles. We have extended the original model by including SUSY breaking terms consistent with all symmetry requirements. Our model is an effective theory, valid at energy scales below a cutoff $\Lambda_f \approx \Lambda_L$, where we have derived the spectrum of SUSY particles, in the slepton sector, under the assumption that the SUSY breaking scale is larger than Λ_f . It provides an example of a model in which the slepton mass matrices at the scale Λ_f are not universal. Left-handed sleptons are approximately universal, with a small departure from universality controlled by u , the flavour symmetry breaking parameter. Right-handed sleptons have soft masses of the same order, but the relative difference among them is expected to be of order one. Off-diagonal elements in both sectors, as well as in the RL block, are small and have a characteristic pattern in

terms of powers of u . This structure is maintained by the effects coming from the RG running from $\Lambda_f \approx \Lambda_L$ down to the electroweak scale. The symmetry breaking parameter u lies in a restricted range around few per cent and has a size similar to the reactor mixing angle θ_{13} . We have exploited the knowledge of the slepton mass matrices to compute the normalized branching ratios R_{ij} for the transitions $\mu \rightarrow e\gamma$, $\tau \rightarrow \mu\gamma$ and $\tau \rightarrow e\gamma$. At variance with other models based on flavour symmetries we found $R_{\mu e} \approx R_{\tau\mu} \approx R_{\tau e}$ and, given the present limit on $R_{\mu e}$, these rare τ decays are practically unobservable in our model. On a more theoretical side, the scaling $R_{ij} \propto u^2$, found in the MI approximation, violates an expectation based on an effective Lagrangian approach, which suggested $R_{ij} \propto u^4$ in the limit of massless final charged lepton. We have identified the source of such a violation in a single, flavour independent, contribution of the RL block of the slepton mass matrix. Such a contribution originates from the VEVs of the auxiliary components of the flavon supermultiplets. We have classified the conditions under which this universal contribution is absent.

In a numerical analysis of $R_{\mu e}$ we found that already the current bound from the MEGA experiment requires the parameter u to be small or $\tan\beta$ to be small for SUSY mass parameters m_{SUSY} and $m_{1/2}$ below 1000 GeV, to guarantee detection of sparticles at LHC. Applying the prospective MEG bound tightens the parameter space of our model even more to small u and $\tan\beta$ or requires mass parameters m_{SUSY} and $m_{1/2}$ above 1000 GeV. Furthermore, we showed that the deviation of the experimentally observed value of the magnetic moment of the muon from the SM one cannot be naturally explained in our framework, for $BR(\mu \rightarrow e\gamma)$ below the current bound. The maximal value of δa_μ in our model is around 100×10^{-11} for $BR(\mu \rightarrow e\gamma) \lesssim 10^{-11}$.

Acknowledgments

We thank Lorenzo Calibbi, Stefano Rigolin and Fabio Zwirner for many useful discussions. We recognize that this work has been partly supported by the European Commission under contracts PITN-GA-2009-237920 (UNILHC) and MRTN-CT-2006-035505.

Appendix A The group A_4

The group A_4 is generated by two elements S and T obeying the relations [14]:

$$S^2 = (ST)^3 = T^3 = 1 \quad . \quad (99)$$

It has three independent one-dimensional representations, 1 , $1'$ and $1''$ and one three-dimensional representation 3 . The one-dimensional representations are given by:

$$\begin{aligned} 1 \quad S &= 1 \quad T = 1 \quad , \\ 1' \quad S &= 1 \quad T = e^{i4\pi/3} \equiv \omega^2 \quad , \\ 1'' \quad S &= 1 \quad T = e^{i2\pi/3} \equiv \omega \quad . \end{aligned} \quad (100)$$

The three-dimensional representation, in a basis where the generator T is diagonal, is given by:

$$T = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \omega^2 & 0 \\ 0 & 0 & \omega \end{pmatrix}, \quad S = \frac{1}{3} \begin{pmatrix} -1 & 2 & 2 \\ 2 & -1 & 2 \\ 2 & 2 & -1 \end{pmatrix} \quad . \quad (101)$$

The multiplication rule for triplet representations is the following:

$$3 \times 3 = 1 + 1' + 1'' + 3_S + 3_A \quad (102)$$

If we denote by:

$$a = (a_1, a_2, a_3) \quad , \quad b = (b_1, b_2, b_3) \quad (103)$$

two triplets, the singlets contained in their product are given by:

$$\begin{aligned} 1 &\equiv (ab) = (a_1b_1 + a_2b_3 + a_3b_2) \\ 1' &\equiv (ab)' = (a_3b_3 + a_1b_2 + a_2b_1) \\ 1'' &\equiv (ab)'' = (a_2b_2 + a_1b_3 + a_3b_1) \end{aligned} \quad (104)$$

The two triplets can be separated into a symmetric and an antisymmetric part:

$$\begin{aligned} 3_S \equiv (ab)_S &= \frac{1}{3}(2a_1b_1 - a_2b_3 - a_3b_2, 2a_3b_3 - a_1b_2 - a_2b_1, 2a_2b_2 - a_1b_3 - a_3b_1) \\ 3_A \equiv (ab)_A &= \frac{1}{2}(a_2b_3 - a_3b_2, a_1b_2 - a_2b_1, a_3b_1 - a_1b_3) \end{aligned} \quad (105)$$

Moreover, if c , c' and c'' are singlets transforming as 1 , $1'$ and $1''$, and $a = (a_1, a_2, a_3)$ is a triplet, then the products ac , ac' and ac'' are triplets explicitly given by (a_1c, a_2c, a_3c) , (a_3c', a_1c', a_2c') and (a_2c'', a_3c'', a_1c'') , respectively. Note that due to the choice of complex representation matrices for the real representation 3 the conjugate $\bar{a}$ of $a \sim 3$ does not transform as 3 , but rather $(\bar{a}_1, \bar{a}_3, \bar{a}_2)$ transforms as triplet under A_4 . The reason for this is that $T^* = U^T T U$ and $S^* = U^T S U = S$ where U is the matrix which exchanges the second and third row and column.

Appendix B Canonical normalization of the kinetic terms and diagonalization of the charged lepton mass matrix m_l

We perform the following transformations on the superfields: the kinetic terms are canonically normalized, i.e. we find the basis in which the matrices K and K^c , shown in eqs. (37,38), are unit matrices, and in a second step the charged lepton mass matrix m_l , eq. (44), is diagonalized. As explained in the main text, we perform these transformations not only on the lepton fields, but also on the sleptons in order to ensure that the gaugino-lepton-slepton vertices do not violate flavour at this stage.

To diagonalize the hermitian matrices K and K^c we apply the unitary transformations W and W^c :

$$W^\dagger K W = \text{diag} \quad \text{and} \quad (W^c)^\dagger K^c W^c = \text{diag} . \quad (106)$$

Normalizing K and K^c requires a rescaling of the fields via the real (diagonal) matrices R and R^c :

$$R W^\dagger K W R = \mathbb{1} \quad \text{and} \quad R^c (W^c)^\dagger K^c W^c R^c = \mathbb{1} . \quad (107)$$

The superfields l and l^c ($l^c = (e^c, \mu^c, \tau^c)$ as above) are expressed as:

$$l = W R l' \quad \text{and} \quad l^c = W^c R^c l'^c \quad (108)$$

so that the kinetic terms for leptons and sleptons are in their canonical form, i.e. eq. (36) becomes:

$$i \bar{l}'_i \bar{\sigma}^\mu D_\mu l'_i + i \bar{l}'^{c'}_i \bar{\sigma}^\mu D_\mu l'^{c'}_i + |D_\mu \tilde{l}'_i|^2 + |D_\mu \tilde{l}'^{c'}_i|^2 .$$

The mass matrices for leptons and sleptons in this basis read:

$$l^c m_l l = l'^c R^c (W^c)^T m_l W R l' \equiv l'^c m'_l l' , \quad (109)$$

and ¹³

$$\begin{aligned} \tilde{l}^c m_{RL}^2 \tilde{l} &= \tilde{l}'^c R^c (W^c)^T m_{RL}^2 W R \tilde{l}' , \\ \tilde{l} m_{LL}^2 \tilde{l} &= \tilde{l}' R W^\dagger m_{LL}^2 W R \tilde{l}' , \\ \tilde{l}^c m_{RR}^2 \tilde{l}^c &= \tilde{l}'^c R^c (W^c)^T m_{RR}^2 W^{c*} R^c \tilde{l}'^c . \end{aligned} \quad (110)$$

We diagonalize the resulting mass matrix m'_l of the charged leptons by the usual bi-unitary transformation:

$$U^T m'_l V = \text{diag}(m_e, m_\mu, m_\tau) \quad (111)$$

and arrive at the mass eigenbasis l'' and l''^c :

$$l'^c = U l''^c \quad \text{and} \quad l' = V l'' . \quad (112)$$

¹³Note that the matrix m_{LL}^2 stands for both, the mass matrix of the left-handed charged sleptons and the one of the sneutrinos.

Finally, the slepton mass matrices m_{RL}^2 , m_{LL}^2 and m_{RR}^2 are given as:

$$\begin{aligned}\tilde{l}^c m_{RL}^2 \tilde{l} &= \tilde{l}^{c''} [U^T R^c (W^c)^T m_{RL}^2 W R V] \tilde{l}'' \equiv \tilde{l}^{c''} \hat{m}_{RL}^2 \tilde{l}'' , \\ \tilde{\bar{l}} m_{LL}^2 \tilde{l} &= \tilde{\bar{l}}'' [V^\dagger R W^\dagger m_{LL}^2 W R V] \tilde{l}'' \equiv \tilde{\bar{l}}'' \hat{m}_{LL}^2 \tilde{l}'' , \\ \tilde{l}^c m_{RR}^2 \tilde{\bar{l}}^c &= \tilde{l}^{c''} [U^T R^c (W^c)^T m_{RR}^2 W^{c*} R^c U^\star] \tilde{\bar{l}}^{c''} \equiv \tilde{l}^{c''} \hat{m}_{RR}^2 \tilde{\bar{l}}^{c''} .\end{aligned}\tag{113}$$

As we assume for the actual calculation of $\hat{m}_{RL}^2$, $\hat{m}_{LL}^2$ and $\hat{m}_{RR}^2$ that all couplings involved are real, the matrices W , W^c , U and V turn out to be orthogonal instead of unitary. Furthermore, we express the small parameter u in terms of t as $u = xt$ with $x \leq 1$ according to eq. (15) and eq. (19). We then can do the calculation in just one expansion parameter t .¹⁴ In the course of the calculation we pose the following requirements: the kinetic terms are canonically normalized up to and including $\mathcal{O}(t^5)$, m_l' is diagonal also up to and including $\mathcal{O}(t^5)$, and the matrices W , W^c , U and V are orthogonal up to the same order. These calculations have been checked by using two independent methods.

Appendix C Notations and one-loop formulae for R_{ij} and δa_μ^{SUSY}

In this part we fix the notations and we report the formulae for R_{ij} and for δa_μ^{SUSY} which we have used in section 5. The main references are [29–32] and we follow these.

The mass matrix of the charginos is given by:

$$- \mathcal{L}_m \supset \left(\begin{array}{cc} \widetilde{W}_R^- & \widetilde{H}_{2R}^- \end{array} \right) M_c \left(\begin{array}{c} \widetilde{W}_L^- \\ \widetilde{H}_{1L}^- \end{array} \right) + h.c.\tag{114}$$

with

$$M_c = \left(\begin{array}{cc} M_2 & \sqrt{2} m_W \cos \beta \\ \sqrt{2} m_W \sin \beta & \mu \end{array} \right) .\tag{115}$$

This matrix is diagonalized by 2×2 rotation matrices O_L and O_R as:

$$O_R M_c O_L^T = \text{diag} \left(M_{\tilde{\chi}_1^-}, M_{\tilde{\chi}_2^-} \right) ,\tag{116}$$

where the diagonalizing matrices connect mass and interaction eigenstates in the following way:

$$\left(\begin{array}{c} \tilde{\chi}_{1L}^- \\ \tilde{\chi}_{2L}^- \end{array} \right) = O_L \left(\begin{array}{c} \widetilde{W}_L^- \\ \widetilde{H}_{1L}^- \end{array} \right) , \quad \left(\begin{array}{c} \tilde{\chi}_{1R}^- \\ \tilde{\chi}_{2R}^- \end{array} \right) = O_R \left(\begin{array}{c} \widetilde{W}_R^- \\ \widetilde{H}_{2R}^- \end{array} \right)\tag{117}$$

and the mass eigenstates are written as $\tilde{\chi}_A^- = \tilde{\chi}_{AL}^- + \tilde{\chi}_{AR}^-$ ($A = 1, 2$) with masses $M_{\tilde{\chi}_A^-}$.

The neutralino mass matrix is given by:

$$- \mathcal{L}_m \supset \frac{1}{2} \left(\begin{array}{cccc} \tilde{B}_L & \widetilde{W}_L^0 & \tilde{H}_{1L}^0 & \tilde{H}_{2L}^0 \end{array} \right) M_N \left(\begin{array}{c} \tilde{B}_L \\ \widetilde{W}_L^0 \\ \tilde{H}_{1L}^0 \\ \tilde{H}_{2L}^0 \end{array} \right) + h.c.\tag{118}$$

¹⁴The different factors of t and u are recovered in the final result by replacing x with $\frac{u}{t}$.

with

$$M_N = \begin{pmatrix} M_1 & 0 & -m_Z \sin \theta_W \cos \beta & m_Z \sin \theta_W \sin \beta \\ 0 & M_2 & m_Z \cos \theta_W \cos \beta & -m_Z \cos \theta_W \sin \beta \\ -m_Z \sin \theta_W \cos \beta & m_Z \cos \theta_W \cos \beta & 0 & -\mu \\ m_Z \sin \theta_W \sin \beta & -m_Z \cos \theta_W \sin \beta & -\mu & 0 \end{pmatrix} \quad (119)$$

We can diagonalize M_N by a rotation matrix O_N :

$$O_N M_N O_N^T = \text{diag} \left(M_{\tilde{\chi}_1^0}, M_{\tilde{\chi}_2^0}, M_{\tilde{\chi}_3^0}, M_{\tilde{\chi}_4^0} \right), \quad (120)$$

where O_N connects mass and interaction eigenstates in the following way:

$$\begin{pmatrix} \tilde{\chi}_{1L}^0 \\ \tilde{\chi}_{2L}^0 \\ \tilde{\chi}_{3L}^0 \\ \tilde{\chi}_{4L}^0 \end{pmatrix} = O_N \begin{pmatrix} \tilde{B}_L \\ \tilde{W}_L^0 \\ \tilde{H}_{1L}^0 \\ \tilde{H}_{2L}^0 \end{pmatrix} \quad (121)$$

and the mass eigenstates are given by $\tilde{\chi}_A^0 = \tilde{\chi}_{AL}^0 + \tilde{\chi}_{AR}^0$ ($A = 1, 2, 3, 4$) with masses $M_{\tilde{\chi}_A^0}$. The mass matrices for the charged sleptons and for sneutrinos are given by:

$$-\mathcal{L}_m \supset (\bar{\tilde{l}} \quad \tilde{l}^c) \hat{\mathcal{M}}_e^2 \begin{pmatrix} \tilde{l} \\ \tilde{l}^c \end{pmatrix} + \tilde{\nu} \hat{m}_{\nu LL}^2 \tilde{\nu} \quad (122)$$

with

$$\hat{\mathcal{M}}_e^2 = \begin{pmatrix} \hat{m}_{eLL}^2 & \hat{m}_{eLR}^2 \\ \hat{m}_{eRL}^2 & \hat{m}_{eRR}^2 \end{pmatrix} \quad (123)$$

where $\hat{m}_{(e,\nu)LL}^2$ and $\hat{m}_{eRR}^2$ are in general hermitian matrices and $\hat{m}_{eLR}^2 = (\hat{m}_{eRL}^2)^\dagger$. We diagonalize the mass matrix $\hat{\mathcal{M}}_e^2$ by a 6×6 rotation matrix $U^{\tilde{l}}$ as:

$$U^{\tilde{l}} \hat{\mathcal{M}}_e^2 U^{\tilde{l}T} = m_{\tilde{l}}^2 \quad (124)$$

where the mass eigenstates are:

$$\tilde{l}_X = U_{X,i}^{\tilde{l}} \tilde{l}_i + U_{X,i+3}^{\tilde{l}} \tilde{l}_i^c \quad (125)$$

with masses $m_{\tilde{l}_X}^2$ ($X = 1, \dots, 6$).

Analogously, the sneutrino mass matrix is diagonalized by:

$$U^{\tilde{\nu}} \hat{m}_{\nu LL}^2 U^{\tilde{\nu}T} = m_{\tilde{\nu}}^2 \quad (126)$$

where the mass eigenstates are:

$$\tilde{\nu}_X = U_{X,i}^{\tilde{\nu}} \tilde{\nu}_i \quad (127)$$

with masses $m_{\tilde{\nu}_X}^2$ ($X = 1, 2, 3$).

The normalized branching ratios, R_{ij} , for the LFV transitions $l_i \rightarrow l_j \gamma$ are:

$$R_{ij} = \frac{BR(l_i \rightarrow l_j \gamma)}{BR(l_i \rightarrow l_j \nu_i \bar{\nu}_j)} = \frac{48\pi^3 \alpha}{G_F^2} (|A_2^L|^2 + |A_2^R|^2) \quad (128)$$

and the decay rates are given by:

$$\Gamma(l_i \rightarrow l_j \nu_i \bar{\nu}_j) = \frac{G_F^2}{192\pi^3} m_i^5 \quad , \quad \Gamma(l_i \rightarrow l_j \gamma) = \frac{e^2}{16\pi} m_i^5 (|A_2^L|^2 + |A_2^R|^2) \quad . \quad (129)$$

Each coefficient $A_2^{L,R}$ can be written as a sum of two terms:

$$A_2^{L,R} = A_2^{(n)L,R} + A_2^{(c)L,R} \quad , \quad (130)$$

where $A_2^{(n)L,R}$ and $A_2^{(c)L,R}$ stand for the contributions from the neutralino and from the chargino loops, respectively. These coefficients are explicitly given by:

$$A_2^{(n)L} = \frac{1}{32\pi^2} \frac{1}{m_{\tilde{l}_X}^2} \left[N_{jAX}^L \bar{N}_{iAX}^L g_{1n}(x_{AX}) + N_{jAX}^R \bar{N}_{iAX}^R \frac{m_j}{m_i} g_{1n}(x_{AX}) + N_{jAX}^L \bar{N}_{iAX}^R \frac{M_{\tilde{\chi}_A^0}}{m_i} g_{2n}(x_{AX}) \right] \quad (131)$$

and $A_2^{(n)R} = A_2^{(n)L}|_{L \leftrightarrow R}$ with $x_{AX} = M_{\tilde{\chi}_A^0}^2/m_{\tilde{l}_X}^2$, and

$$A_2^{(c)L} = -\frac{1}{32\pi^2} \frac{1}{m_{\tilde{\nu}_X}^2} \left[C_{jAX}^L \bar{C}_{iAX}^L g_{1c}(x_{AX}) + C_{jAX}^R \bar{C}_{iAX}^R \frac{m_j}{m_i} g_{1c}(x_{AX}) + C_{jAX}^L \bar{C}_{iAX}^R \frac{M_{\tilde{\chi}_A^-}}{m_i} g_{2c}(x_{AX}) \right] \quad (132)$$

and $A_2^{(c)R} = A_2^{(c)L}|_{L \leftrightarrow R}$ with $x_{AX} = M_{\tilde{\chi}_A^-}^2/m_{\tilde{\nu}_X}^2$.

The terms N_{iAX} and C_{iAX} and the loop functions g_{in} and g_{ic} read as follows:

$$N_{iAX}^L = -\frac{g_2}{\sqrt{2}} \left\{ [-(O_N)_{A,2} - (O_N)_{A,1} \tan \theta_W] U_{X,i}^{\tilde{l}} + \frac{m_i}{m_W \cos \beta} (O_N)_{A,3} U_{X,i+3}^{\tilde{l}} \right\} \quad (133)$$

$$N_{iAX}^R = -\frac{g_2}{\sqrt{2}} \left\{ \frac{m_i}{m_W \cos \beta} (O_N)_{A,3} U_{X,i}^{\tilde{l}} + 2(O_N)_{A,1} \tan \theta_W U_{X,i+3}^{\tilde{l}} \right\} \quad (134)$$

$$C_{iAX}^L = -g_2 (O_R)_{A,1} U_{X,i}^{\tilde{\nu}} \quad (135)$$

$$C_{iAX}^R = g_2 \frac{m_i}{\sqrt{2} m_W \cos \beta} (O_L)_{A,2} U_{X,i}^{\tilde{\nu}} \quad (136)$$

and

$$g_{1n}(x_{AX}) = \frac{1}{6(1-x_{AX})^4} (1 - 6x_{AX} + 3x_{AX}^2 + 2x_{AX}^3 - 6x_{AX}^2 \ln x_{AX}) \quad (137)$$

$$g_{2n}(x_{AX}) = \frac{1}{(1-x_{AX})^3} (1 - x_{AX}^2 + 2x_{AX} \ln x_{AX}) \quad (138)$$

$$g_{1c}(x_{AX}) = \frac{1}{6(1-x_{AX})^4} (2 + 3x_{AX} - 6x_{AX}^2 + x_{AX}^3 + 6x_{AX} \ln x_{AX}) \quad (139)$$

$$g_{2c}(x_{AX}) = \frac{1}{(1-x_{AX})^3} (-3 + 4x_{AX} - x_{AX}^2 - 2 \ln x_{AX}) \quad . \quad (140)$$

We note that the functions f_{in} and f_{ic} , displayed in section 4, are related to the loop functions g_{in} and g_{ic} , mostly through taking the first derivative.

The deviation of the muon anomalous magnetic moment, δa_μ^{SUSY} , due to SUSY contributions can be written as:

$$\delta a_{\ell_i}^{SUSY} = \frac{g_{\ell_i}^{(n)} + g_{\ell_i}^{(c)}}{2} \quad (141)$$

with

$$g_{\ell_i}^{(n,c)} = g_{\ell_i}^{(n,c)L} + g_{\ell_i}^{(n,c)R} . \quad (142)$$

These terms are explicitly given by:

$$g_{\ell_i}^{(c)L} = \frac{1}{16\pi^2} \frac{m_i^2}{m_{\tilde{\nu}_X}^2} \left[C_{iAX}^L \bar{C}_{iAX}^L g_{1c}(x_{AX}) + C_{iAX}^R \bar{C}_{iAX}^R g_{1c}(x_{AX}) + C_{iAX}^L \bar{C}_{iAX}^R \frac{M_{\tilde{\chi}_A^-}}{m_i} g_{2c}(x_{AX}) \right] \quad (143)$$

and $g_{\ell_i}^{(c)R} = g_{\ell_i}^{(c)L}|_{L \leftrightarrow R}$ with $x_{AX} = M_{\tilde{\chi}_A^-}^2/m_{\tilde{\nu}_X}^2$, and

$$g_{\ell_i}^{(n)L} = -\frac{1}{16\pi^2} \frac{m_i^2}{m_{\tilde{l}_X}^2} \left[N_{iAX}^L \bar{N}_{iAX}^L g_{1n}(x_{AX}) + N_{iAX}^R \bar{N}_{iAX}^R g_{1n}(x_{AX}) + N_{iAX}^L \bar{N}_{iAX}^R \frac{M_{\tilde{\chi}_A^0}}{m_i} g_{2n}(x_{AX}) \right] \quad (144)$$

and $g_{\ell_i}^{(n)R} = g_{\ell_i}^{(n)L}|_{L \leftrightarrow R}$ with $x_{AX} = M_{\tilde{\chi}_A^0}^2/m_{\tilde{l}_X}^2$. The terms N_{iAX} and C_{iAX} and the functions g_{in} and g_{ic} have been already introduced in eqs. (133-136) and in eqs. (137-140).
